contents

preface xvii
acknowledgments xix
about this book xx
about the authors xxii

1 Before you begin 1

- 1.1 Why you can't afford to ignore PowerShell 1
 - Life without PowerShell* 2 ▪ *Life with PowerShell* 2
- 1.2 And now, it's just "PowerShell" 3
- 1.3 Is this book for you? 3
- 1.4 How to use this book 4
 - The main chapters* 4 ▪ *Hands-on labs* 5 ▪ *Code samples* 5 ▪ *Supplementary materials* 5 ▪ *Further exploration* 5 ▪ *Above and beyond* 5
- 1.5 Setting up your lab environment 6
- 1.6 Installing Windows PowerShell 7
- 1.7 Contacting us 8
- 1.8 Being immediately effective with PowerShell 8

2 Meet PowerShell 9

- 2.1 Choose your weapon 9
 - The console window* 11 ▪ *The Integrated Scripting Environment* 13

2.2	It's typing class all over again	15
2.3	Common points of confusion	17
2.4	What version is this?	17
2.5	Lab	18

3 Using the help system 20

3.1	The help system: how you discover commands	20
3.2	Updatable help	22
3.3	Asking for help	23
3.4	Using help to find commands	24
3.5	Interpreting the help	26
	<i>Parameter sets and common parameters</i>	26
	<i>Optional and mandatory parameters</i>	28
	<i>Positional parameters</i>	28
	<i>Parameter values</i>	30
	<i>Finding command examples</i>	33
3.6	Accessing “about” topics	33
3.7	Accessing online help	34
3.8	Lab	34
3.9	Lab answers	36

4 Running commands 37

4.1	Not scripting, but running commands	37
4.2	The anatomy of a command	38
4.3	The cmdlet naming convention	39
4.4	Aliases: nicknames for commands	40
4.5	Taking shortcuts	42
	<i>Truncating parameter names</i>	42
	<i>Using parameter name aliases</i>	42
	<i>Using positional parameters</i>	42
4.6	Cheating a bit: Show-Command	44
4.7	Support for external commands	44
4.8	Dealing with errors	48
4.9	Common points of confusion	49
	<i>Typing cmdlet names</i>	49
	<i>Typing parameters</i>	49
4.10	Lab	50

5 Working with providers 51

5.1	What are providers?	51
-----	---------------------	----

- 5.2 Understanding how the filesystem is organized 53
- 5.3 Understanding how the filesystem is like other data stores 55
- 5.4 Navigating the filesystem 55
- 5.5 Using wildcards and literal paths 57
- 5.6 Working with other providers 58
- 5.7 Lab 61
- 5.8 Further exploration 62
- 5.9 Lab answers 62

6 *The pipeline: connecting commands* 63

- 6.1 Connecting one command to another: less work for you 63
- 6.2 Exporting to a CSV or an XML file 64
 - Exporting to CSV* 65 ▪ *Exporting to XML* 66
 - Comparing files* 67
- 6.3 Piping to a file or a printer 69
- 6.4 Converting to HTML 70
- 6.5 Using cmdlets that modify the system: killing processes and stopping services 71
- 6.6 Common points of confusion 72
- 6.7 Lab 74
- 6.8 Lab answers 75

7 *Adding commands* 76

- 7.1 How one shell can do everything 76
- 7.2 About product-specific “management shells” 77
- 7.3 Extensions: finding and adding snap-ins 78
- 7.4 Extensions: finding and adding modules 80
- 7.5 Command conflicts and removing extensions 82
- 7.6 On non-Windows operating systems 83
- 7.7 Playing with a new module 83
- 7.8 Profile scripts: preloading extensions when the shell starts 85
- 7.9 Getting modules from the internet 86
- 7.10 Common points of confusion 87

- 7.11 Lab 87
- 7.12 Lab answers 88

8 *Objects: data by another name 89*

- 8.1 What are objects? 89
- 8.2 Understanding why PowerShell uses objects 90
- 8.3 Discovering objects: Get-Member 92
- 8.4 Using object attributes, or properties 94
- 8.5 Using object actions, or methods 94
- 8.6 Sorting objects 95
- 8.7 Selecting the properties you want 96
- 8.8 Objects until the end 97
- 8.9 Common points of confusion 99
- 8.10 Lab 99
- 8.11 Lab answers 100

9 *The pipeline, deeper 101*

- 9.1 The pipeline: enabling power with less typing 101
- 9.2 How PowerShell passes data down the pipeline 101
- 9.3 Plan A: pipeline input ByValue 102
- 9.4 Plan B: pipeline input ByPropertyName 106
- 9.5 When things don't line up: custom properties 111
- 9.6 Parenthetical commands 114
- 9.7 Extracting the value from a single property 115
- 9.8 Lab 121
- 9.9 Further exploration 122
- 9.10 Lab answers 122

10 *Formatting—and why it's done on the right 123*

- 10.1 Formatting: making what you see prettier 123
- 10.2 Working with the default formatting 124
- 10.3 Formatting tables 127
- 10.4 Formatting lists 128
- 10.5 Formatting wide lists 129
- 10.6 Creating custom columns and list entries 130

10.7	Going out: to a file, a printer, or the host	133
10.8	Another out: GridViews	133
10.9	Common points of confusion	133
	<i>Always format right 133 ▪ One type of object at a time, please 135</i>	
10.10	Lab	137
10.11	Further exploration	137
10.12	Lab answers	138

11 *Filtering and comparisons 139*

11.1	Making the shell give you just what you need	139
11.2	Filtering left	140
11.3	Using comparison operators	140
11.4	Filtering objects out of the pipeline	142
11.5	Using the iterative command-line model	144
11.6	Common points of confusion	145
	<i>Filter left, please 145 ▪ When \$_ is allowed 146</i>	
11.7	Lab	146
11.8	Further exploration	147
11.9	Lab answers	147

12 *A practical interlude 148*

12.1	Defining the task	148
12.2	Finding the commands	148
12.3	Learning to use the commands	150
12.4	Tips for teaching yourself	151
12.5	Lab	152
12.6	Lab answer	152

13 *Remote control: one-to-one, and one-to-many 153*

13.1	The idea behind remote PowerShell	154
13.2	WinRM overview	155
13.3	Using Enter-PSSession and Exit-PSSession for one-to-one remoting	159
13.4	Using Invoke-Command for one-to-many remoting	161

13.5 Differences between remote and local commands 163

*Invoke-Command vs. -computerName 164 ▪ Local vs.
remote processing 165 ▪ Deserialized objects 166*

13.6 But wait, there's more 167

13.7 Remote options 168

13.8 Common points of confusion 168

13.9 Lab 169

13.10 Further exploration 170

13.11 Lab answers 170

14 Using Windows Management Instrumentation and CIM 171

14.1 WMI essentials 172

14.2 The bad news about WMI 173

14.3 Exploring WMI 174

14.4 Choose your weapon: WMI or CIM 177

14.5 Using Get-WmiObject 178

14.6 Using Get-CimInstance 182

14.7 WMI documentation 182

14.8 Common points of confusion 182

14.9 Lab 183

14.10 Further exploration 184

14.11 Lab answers 184

15 Multitasking with background jobs 185

15.1 Making PowerShell do multiple things at the same time 185

15.2 Synchronous vs. asynchronous 186

15.3 Creating a local job 187

15.4 WMI, as a job 188

15.5 Remoting, as a job 189

15.6 Getting job results 189

15.7 Working with child jobs 192

15.8 Commands for managing jobs 194

15.9 Scheduled jobs 196

15.10 Common points of confusion 197

- 15.11 Lab 198
- 15.12 Lab answers 199

16 *Working with many objects, one at a time* 200

- 16.1 Automation for mass management 200
- 16.2 The preferred way: “batch” cmdlets 201
- 16.3 The CIM/WMI way: invoking methods 202
- 16.4 The backup plan: enumerating objects 206
- 16.5 Common points of confusion 211
 - Which way is the right way?* 211 ▪ *WMI methods vs. cmdlets* 212 ▪ *Method documentation* 213
ForEach-Object confusion 213
- 16.6 Lab 214
- 16.7 Lab answers 214

17 *Security alert!* 216

- 17.1 Keeping the shell secure 216
- 17.2 Windows PowerShell security goals 217
- 17.3 Execution policy and code signing 218
 - Execution policy settings* 218 ▪ *Digital code signing* 222
- 17.4 Other security measures 225
- 17.5 Other security holes? 225
- 17.6 Security recommendations 226
- 17.7 Lab 227

18 *Variables: a place to store your stuff* 228

- 18.1 Introduction to variables 228
- 18.2 Storing values in variables 229
- 18.3 Using variables: fun tricks with quotes 231
- 18.4 Storing many objects in a variable 233
 - Working with single objects in a variable* 234 ▪ *Working with multiple objects in a variable* 235 ▪ *Other ways to work with multiple objects* 236 ▪ *Unrolling properties and methods in PowerShell v3* 237
- 18.5 More tricks with double quotes 237
- 18.6 Declaring a variable’s type 239

- 18.7 Commands for working with variables 241
- 18.8 Variable best practices 242
- 18.9 Common points of confusion 242
- 18.10 Lab 242
- 18.11 Further exploration 243
- 18.12 Lab answer 243

19 *Input and output 244*

- 19.1 Prompting for, and displaying, information 244
- 19.2 Read-Host 245
- 19.3 Write-Host 248
- 19.4 Write-Output 249
- 19.5 Other ways to write 251
- 19.6 Lab 252
- 19.7 Further exploration 252
- 19.8 Lab answers 252

20 *Sessions: remote control with less work 253*

- 20.1 Making PowerShell remoting a bit easier 253
- 20.2 Creating and using reusable sessions 254
- 20.3 Using sessions with Enter-PSSession 255
- 20.4 Using sessions with Invoke-Command 257
- 20.5 Implicit remoting: importing a session 258
- 20.6 Using disconnected sessions 260
- 20.7 Lab 261
- 20.8 Further exploration 262
- 20.9 Lab answers 262

21 *You call this scripting? 263*

- 21.1 Not programming, more like batch files 263
- 21.2 Making commands repeatable 264
- 21.3 Parameterizing commands 265
- 21.4 Creating a parameterized script 267
- 21.5 Documenting your script 268
- 21.6 One script, one pipeline 270

- 21.7 A quick look at scope 273
- 21.8 Lab 274
- 21.9 Lab answer 275

22 *Improving your parameterized script* 276

- 22.1 Starting point 276
- 22.2 Getting PowerShell to do the hard work 277
- 22.3 Making parameters mandatory 278
- 22.4 Adding parameter aliases 280
- 22.5 Validating parameter input 281
- 22.6 Adding the warm and fuzzies with verbose output 282
- 22.7 Lab 284
- 22.8 Lab answer 284

23 *Advanced remoting configuration* 286

- 23.1 Using other endpoints 286
- 23.2 Creating custom endpoints 287
 - Creating the session configuration* 288
 - Registering the session* 289
- 23.3 Enabling multihop remoting 291
- 23.4 Digging deeper into remoting authentication 292
 - Defaults for mutual authentication* 292 ▪ *Mutual authentication via SSL* 293 ▪ *Mutual authentication via TrustedHosts* 293
- 23.5 Lab 294
- 23.6 Lab answer 295

24 *Using regular expressions to parse text files* 296

- 24.1 The purpose of regular expressions 297
- 24.2 A regex syntax primer 297
- 24.3 Using regex with -Match 299
- 24.4 Using regex with Select-String 299
- 24.5 Lab 301
- 24.6 Further exploration 301
- 24.7 Lab answers 302

25 Additional random tips, tricks, and techniques 303

- 25.1 Profiles, prompts, and colors: customizing the shell 303
 - PowerShell profiles* 303 ▪ *Customizing the prompt* 305
 - Tweaking colors* 306
- 25.2 Operators: -as, -is, -replace, -join, -split, -in, -contains 307
 - as and -is* 307 ▪ *-replace* 308 ▪ *-join and -split* 308
 - contains and -in* 309
- 25.3 String manipulation 310
- 25.4 Date manipulation 311
- 25.5 Dealing with WMI dates 312
- 25.6 Setting default parameter values 313
- 25.7 Playing with script blocks 315
- 25.8 More tips, tricks, and techniques 315

26 Using someone else's script 316

- 26.1 The script 317
- 26.2 It's a line-by-line examination 321
- 26.3 Lab 321
- 26.4 Lab answer 323

27 Never the end 325

- 27.1 Ideas for further exploration 325
- 27.2 "Now that I've read the book, where do I start?" 326
- 27.3 Other resources you'll grow to love 327

28 PowerShell cheat sheet 328

- 28.1 Punctuation 328
- 28.2 Help file 331
- 28.3 Operators 332
- 28.4 Custom property and column syntax 332
- 28.5 Pipeline parameter input 333
- 28.6 When to use \$_ 334

appendix Review labs 335

index 347

****preface****

We've been teaching and writing about Windows PowerShell for a long time. When Don began contemplating the first edition of this book, he realized that most PowerShell writers and teachers—including himself—were forcing our students to approach the shell as a kind of programming language. Most PowerShell books are into "scripting" by the third or fourth chapter, yet more and more PowerShell students were backing away from that programming-oriented approach. Those students wanted to use the shell as a shell, at least at first, and we weren't delivering a learning experience that matched that desire.

So he decided to take a swing at it. A blog post on the Windows IT Pro website proposed a table of contents for this book, and ample feedback from the blog's readers fine-tuned it into the book you're about to read. He wanted to keep each chapter short, focused, and easy to cover in a short period of time—because we know administrators don't have a lot of free time and often have to learn on the fly. When PowerShell v3 came out, it was obviously a good time to update the book, and Don turned to Jeffery Hicks, a long-time collaborator and fellow MVP, to help out.

We both wanted a book that would focus on PowerShell itself, and not on the myriad technologies that PowerShell touches, like Exchange Server, SQL Server, System Center, and so on. We feel that by learning to use the shell properly, you can teach yourself to administer all of those "PowerShell-ed" server products. So this book focuses on the core of using PowerShell. Even if you're also using a "cookbook" style of book that provides ready-to-use answers for specific administrative tasks, this book will help you understand what those examples are doing. That understanding will make it easier to modify those examples for other purposes, and eventually to construct your own commands and scripts from scratch.

We hope this book won't be the only PowerShell education that you pursue. We've also co-authored *Learn PowerShell Toolmaking in a Month of Lunches*, which offers the same day-at-a-time approach to learning PowerShell's scripting and tool-creation capabilities. You can also find videos we've produced on YouTube and read articles we've authored for sites such as the Petri IT Knowledgebase and Windows IT Pro, not to mention take courses from Pluralsight.

If you need any further help, we encourage you to log on to www.PowerShell.org. We both answer questions in several of the discussion forums there, and we'd be happy to try to get you out of whatever you're stuck on. The site is also a great portal into the robust and active PowerShell community; you can learn about free e-books, the in-person PowerShell and DevOps Summit, and all of the regional and local user groups and PowerShell-related events that happen throughout the year. Get involved—it's a great way to make PowerShell a more powerful part of your career.

Enjoy—and good luck with the shell.

acknowledgments

Books don't write, edit, and publish themselves. Don would like to thank everyone at Manning Publications who decided to take a chance on a different kind of book for Windows PowerShell, and who worked so hard to make the first edition of this book happen. Jeff would like to thank Don for inviting him along for the ride, and the PowerShell community for their enthusiasm and support. Don and Jeff are both grateful to Manning for allowing them to continue the "Month of Lunches" series with this third edition.

Thanks also to the following peer reviewers who read the manuscript during its development and provided feedback: Bennett Scharf, Dave Pawson, David Moravec, Keith Hill, and Rajesh Attaluri. In addition, Erika Bricker, Gerald Mack, Henry Phillips, Hugo Durana, Joseph Tingsanchali, Noreen Dertinger, Olivier Deveault, Stefan Hellweger, Steven Presley, and Tiklu Ganguly provided valuable comments.

Finally, thanks also to James Berkenbile and Trent Whiteley for their technical review of the manuscript and code during production.

about this book

Most of what you need to know about this book is covered in chapter 1, but there are a few things that we should mention up front.

First of all, if you plan to follow along with our examples and complete the hands-on exercises, you'll need a virtual machine or computer running Windows 8.1 or Windows Server 2012, or later. We cover that in more detail in chapter 1. You can get by with Windows 7, but you'll miss out on a few of the hands-on labs.

Second, be prepared to read this book from start to finish, covering each chapter in order. Again, this is something we explain in more detail in chapter 1, but the idea is that each chapter introduces a few new things that you'll need in subsequent chapters. You shouldn't try to push through the whole book—stick with the one chapter per day approach. The human brain can absorb only so much information at once, and by taking on PowerShell in small chunks, you'll learn it a lot faster and more thoroughly.

Third, this book contains a lot of code snippets. Most of them are short, so you should be able to type them easily. In fact, we recommend that you do type them, because doing so will help reinforce an essential PowerShell skill: accurate typing! Longer code snippets are given in listings and are available for download from the book's page on the publisher's website at <https://www.manning.com/books/learn-windows-powershell-in-a-month-of-lunches-third-edition>.

That said, you should be aware of a few conventions. Code always appears in a special font, just as in this example:

```
Get-WmiObject -class Win32_OperatingSystem  
➥-computerName SERVER-R2
```

That example also illustrates the line-continuation character used in this book. It indicates that those two lines should be typed as a single line in PowerShell. In other

words, don't hit Enter or Return after `Win32_OperatingSystem`—keep right on typing. PowerShell allows for long lines, but the pages of this book can hold only so much.

Sometimes you'll also see that code font within the text itself, such as when we write `Get-Command`. That just lets you know that you're looking at a command, parameter, or other element that you would type within the shell.

Fourth is a tricky topic that we'll bring up again in several chapters: the backtick character (`). Here's an example:

```
Invoke-Command -scriptblock { Dir } `  
-computerName SERVER-R2,localhost
```

The character at the end of the first line isn't a stray bit of ink—it's a real character that you would type. On a U.S. keyboard, the backtick (or grave accent) is usually near the upper left, under the Esc key, on the same key as the tilde character (~). When you see the backtick in a code listing, type it exactly as is. Furthermore, when it appears at the end of a line—as in the preceding example—make sure that it's the last character on that line. If you allow any spaces or tabs to appear after it, the backtick won't work correctly, and neither will the code example.

Finally, we'll occasionally direct you to internet resources. Where those URLs are particularly long and difficult to type, we've replaced them with Manning-based shortened URLs that look like <http://mng.bz/S085> (you'll see that one in chapter 1).

Author Online

The purchase of *Learn Windows PowerShell in a Month of Lunches, Third Edition* includes access to a private forum run by Manning Publications where you can make comments about the book, ask technical questions, and receive help from the authors and other users. To access and subscribe to the forum, point your browser to <https://www.manning.com/books/learn-windows-powershell-in-a-month-of-lunches-third-edition> and click the Author Online link. This page provides information on how to get on the forum after you're registered, the kind of help that's available, and the rules of conduct in the forum.

Manning's commitment to our readers is to provide a venue where a meaningful dialogue between individual readers and between readers and the authors can take place. It's not a commitment to any specific amount of participation on the part of the authors, whose contribution to the book's forum remains voluntary (and unpaid). We suggest you try asking the authors some challenging questions, lest their interest stray!

The Author Online forum and the archives of previous discussions will be accessible from the publisher's website as long as the book is in print.

about the authors

DON JONES is a multiple-year recipient of Microsoft’s prestigious Most Valuable Professional (MVP) Award for his work with Windows PowerShell. For five years he wrote the Windows PowerShell column for *Microsoft TechNet Magazine*. He currently blogs at <http://PowerShell.org> and authors the “Decision Maker” column and blog for *Redmond Magazine*. Don is a prolific technology author and has published more than a dozen print books since 2001. He’s now a curriculum director for IT Ops content at Pluralsight, an online video training platform. Don’s first Windows scripting language was KiXtart, going back all the way to the mid-1990s. He quickly graduated to VBScript in 1995 and was one of the first IT pros to start using early releases of a new Microsoft product code-named Monad—which later became Windows PowerShell. Don lives in Las Vegas and, when it gets too hot there, near Duck Creek Village in Utah.

JEFFERY HICKS is an IT veteran with more than 25 years of experience, much of it spent as an IT infrastructure consultant specializing in Microsoft server technologies with an emphasis in automation and efficiency. He is a multiyear recipient of the Microsoft MVP Award in Windows PowerShell. He works today as an independent author, trainer, and consultant. He has taught and presented on PowerShell and the benefits of automation to IT pros all over the world. Jeff has written for numerous online sites and print publications, is a contributing editor at Petri IT Knowledgebase, a Pluralsight author, and a frequent speaker at technology conferences and user groups. You can keep up with Jeff at his blog, <http://jdhitsolutions.com/blog>, and on Twitter (@JeffHicks).

Before you begin

We've been teaching Windows PowerShell since version 1 was released in 2006. Back then, most of the folks using the shell were experienced VBScript users, and they were eager to apply their VBScript skills to learning PowerShell. As a result, we and the other folks who taught the shell, wrote books and articles, and so forth, all adopted a teaching style that takes advantage of prior programming or scripting skills.

But since late 2009, a shift has occurred. More and more administrators who *don't* have prior VBScript experience have started trying to learn the shell. All of a sudden, our old teaching patterns didn't work as well, because we had focused on scripting and programming. That's when we realized that PowerShell isn't a scripting language. It's a command-line shell where you run command-line utilities. Like all good shells, it has scripting capabilities, but you don't have to use them, and you certainly don't have to *start* with them. We started changing our teaching patterns, beginning with the many conferences we speak at each year. Don also implemented these changes into his instructor-led training courseware.

This book is the result of that process, and it's the best that we've yet devised to teach PowerShell to someone who might not have a scripting background (although it certainly doesn't hurt if you do). But before we jump into the instruction, let's set the stage for you.

1.1 Why you can't afford to ignore PowerShell

Batch. KiXtart. VBScript. Let's face it, Windows PowerShell isn't exactly Microsoft's (or anyone else's) first effort at providing automation capabilities to Windows administrators. We think it's valuable to understand why you should care about PowerShell, because when you do, you'll feel comfortable that the time you commit

to learning PowerShell will pay off. Let's start by considering what life was like before PowerShell came along, and look at some of the advantages of using this shell.

1.1.1 **Life without PowerShell**

Windows administrators have always been happy to click around in the graphical user interface (GUI) to accomplish their chores. After all, the GUI is largely the whole point of Windows—the operating system isn't called *Text*, after all. GUIs are great because they enable you to discover what you can do. Don remembers the first time he opened Active Directory Users and Computers. He hovered over icons and read tooltips, pulled down menus, and right-clicked things, all to see what was available. GUIs make learning a tool easier. Unfortunately, GUIs have zero return on that investment. If it takes you five minutes to create a new user in Active Directory (and assuming you're filling in a lot of the fields, that's a reasonable estimate), you'll never get any faster than that. One hundred users will take five hundred minutes—there's no way, short of learning to type and click faster, to make the process go any quicker.

Microsoft has tried to deal with that problem a bit haphazardly, and VBScript was probably its most successful attempt. It might have taken you an hour to write a VBScript that could import new users from a CSV file, but after you'd invested that hour, creating users in the future would take only a few seconds. The problem with VBScript is that Microsoft didn't make a wholehearted effort in supporting it. Microsoft had to remember to make things VBScript accessible, and when developers forgot (or didn't have time), you were stuck. Want to change the IP address of a network adapter by using VBScript? OK, you can. Want to check its link speed? You can't, because nobody remembered to hook that up in a way that VBScript could get to. Sorry. Jeffrey Snover, the architect of Windows PowerShell, calls this *the last mile*. You can do a lot with VBScript (and other, similar technologies), but it tends to let you down at some point, never getting you through that last mile to the finish line.

Windows PowerShell is an express attempt on Microsoft's part to do a better job and to get you through the last mile. And it's been a successful attempt so far. Dozens of product groups within Microsoft have adopted PowerShell, an extensive ecosystem of third parties depend on it, and a global community of experts and enthusiasts are pushing the PowerShell envelope every day.

1.1.2 **Life with PowerShell**

Microsoft's goal for Windows PowerShell is to build 100% of a product's administrative functionality in the shell. Microsoft continues to build GUI consoles, but those consoles are executing PowerShell commands behind the scenes. That approach forces the company to make sure that every possible thing you can do with the product is accessible through the shell. If you need to automate a repetitive task or create a process that the GUI doesn't enable well, you can drop into the shell and take full control for yourself.

Several Microsoft products have already adopted this approach, including Exchange Server 2007 and beyond, SharePoint Server 2010 and later, many of the System Center products, Office 365, and many components of Windows itself. Going forward, more and more products and Windows components will follow this pattern. Windows Server 2012, which was where PowerShell v3 was introduced, is almost completely managed from PowerShell—or by a GUI sitting atop PowerShell. That's why you can't afford to ignore PowerShell: Over the next few years, it'll become the basis for more and more administration. It's already become the foundation for numerous higher-level technologies, including Desired State Configuration (DSC), PowerShell Workflow, and much more. PowerShell is everywhere!

Ask yourself this question: If you were in charge of a team of IT administrators (and perhaps you are), who would you want in your senior, higher-paying positions? Administrators who need several minutes to click their way through a GUI each time they need to perform a task, or ones who can perform tasks in a few seconds after automating them? We already know the answer from almost every other part of the IT world. Ask a Cisco administrator, or an AS/400 operator, or a UNIX administrator. The answer is, “I'd rather have the person who can run things more efficiently from the command line.” Going forward, the Windows world will start to split into two groups: administrators who can use PowerShell, and those who can't. As Don famously said at Microsoft's TechEd 2010 conference, “Your choice is *learn PowerShell, or would you like fries with that?*”

We're glad you've decided to learn PowerShell.

1.2 And now, it's just “PowerShell”

In mid-2016, Microsoft took the previously unthinkable step of open sourcing all of Windows PowerShell. At the same time, it released versions of PowerShell—without the *Windows* attached—for macOS and numerous Linux builds. Amazing! Now, the same object-centric shell is available on many operating systems, and can be evolved and improved by a worldwide community. So for this edition of the book, we decided to make sure we addressed PowerShell on something other than Windows. We still feel that PowerShell's biggest audience will be Windows users, but we also want to make sure you understand how it works on other operating systems.

1.3 Is this book for you?

This book doesn't try to be all things to all people. Microsoft's PowerShell team loosely defines three audiences who use PowerShell:

- Administrators who primarily run commands and consume tools written by others
- Administrators who combine commands and tools into more-complex processes, and perhaps package those as tools that less-experienced administrators can use
- Administrators and developers who create reusable tools and applications

This book is designed primarily for the first audience. We think it's valuable for anyone, even a developer, to understand how the shell is used to run commands. After all, if you're going to create your own tools and commands, you should know the patterns that the shell uses, as they allow you to make tools and commands that work as well as they can within the shell.

If you're interested in creating scripts to automate complex processes, such as new user provisioning, then you'll see how to do that by the end of this book. You'll even see how to get started on creating your own commands that other administrators can use. But this book won't probe the depths of everything that PowerShell can possibly do. Our goal is to get you using the shell and being effective with it in a production environment.

We'll also show you a couple of ways to use PowerShell to connect to external management technologies; Windows Management Instrumentation (WMI) and regular expressions are the two examples that come quickly to mind. For the most part, we're going to introduce only those technologies and focus on how PowerShell connects to them. Those topics deserve their own books (and have them—we'll provide recommendations when we get there), so we concentrate solely on the PowerShell side of things. We'll provide suggestions for further exploration if you'd like to pursue those technologies on your own. In short, this book isn't meant to be the last thing you use to learn about PowerShell, but instead is designed to be a great first step.

1.4 **How to use this book**

The idea behind this book is that you'll read one chapter each day. You don't have to read it during lunch, but each chapter should take you only about 40 minutes to read, giving you an extra 20 minutes to gobble down the rest of your sandwich and practice what the chapter showed you.

1.4.1 **The main chapters**

Of the chapters in this book, chapters 2 through 25 contain the main content, giving you 24 days' worth of lunches to look forward to. You can expect to complete the main content of the book in about a month. Try to stick with that schedule as much as possible, and don't feel the need to read extra chapters in a given day. It's more important that you spend some time practicing what each chapter shows you, because using the shell will help cement what you've learned. Not every chapter requires a full hour, so sometimes you'll be able to spend additional time practicing (and eating lunch) before you have to get back to work. We find that a lot of people learn more quickly when they stick with just one chapter a day, because it gives your brain time to mull over the new ideas, and gives you time to practice them on your own. Don't rush it, and you may find yourself moving more quickly than you thought possible.

1.4.2 Hands-on labs

Most of the main content chapters include a short lab for you to complete. You'll be given instructions, and perhaps a hint or two. The answers for these labs appear at the end of each chapter. But try your best to complete each lab without looking at the answers.

1.4.3 Code samples

Throughout the book, you'll encounter code listings. These are longer PowerShell examples. But don't feel you need to copy them. If you head to www.manning.com and find the page for this book, you'll see a link to download all of the code listings.

1.4.4 Supplementary materials

Don's YouTube channel, YouTube.com/PowerShellDon, contains a bunch of free videos that he made for the original edition of this book—and they're all still 100% applicable. They're a great way to get some short, quick demos. He also hosts videos from recorded conference workshops and more, and they're all worth a look. We also suggest the PowerShell.org channel, YouTube.com/powershellorg, which contains a ton of video content. You'll find recorded sessions from the PowerShell + DevOps Global Summit events, online community webinars, and a lot more. All free!

Jeff does a lot of writing for the Petri IT Knowledgebase (www.petri.com), where you'll find a huge collection of content covering all sorts of PowerShell topics. You might also see whether Jeff has anything new on his YouTube channel, [http://YouTube.com/jdhitsolutions](https://YouTube.com/jdhitsolutions).

1.4.5 Further exploration

A few chapters in this book only skim the surface of some cool technologies, and we end those chapters with suggestions for exploring those technologies on your own. We point out additional resources, including free stuff that you can use to expand your skill set as the need arises.

1.4.6 Above and beyond

As we learned PowerShell, we often wanted to go off on a tangent and explore why something worked the way it did. We didn't learn a lot of extra practical skills that way, but we did gain a deeper understanding of what the shell is and how it works. We've included some of that tangential information throughout the book in sections labeled "Above and beyond." None of those will take you more than a couple of minutes or so to read, but if you're the type of person who likes to know why something works the way it does, they can provide some fun additional facts. If you feel those sections might distract you from the practical stuff, ignore them on your first read-through. You can always come back and explore them later, after you've mastered the chapter's main material.

1.5 Setting up your lab environment

You’re going to be doing a lot of practicing in Windows PowerShell throughout this book, and you’ll want to have a lab environment to work in; please don’t practice in your company’s production environment.

All you’ll need to run most of the examples in this book—and to complete all of the labs—is a copy of Windows that has PowerShell v3 or later installed. We suggest Windows 8.1 or later, or Windows Server 2012 R2 or later, which both come with PowerShell v4. Note that PowerShell might not exist on certain editions of Windows, such as Starter editions. If you’re going to play with PowerShell, you’ll have to invest in a version of Windows that has it. Also note that some of the labs rely on functionality that was new in Windows 8 and Windows Server 2012, so if you’re using something older, things might work differently. At the start of each lab, we tell you what operating system you need in order to complete the lab.

Keep in mind that, throughout this book, we’re assuming you’ll be working on a 64-bit operating system, also referred to as an *x64* operating system. As such, it comes with two copies of Windows PowerShell and the graphically-oriented Windows PowerShell Integrated Scripting Environment (ISE). In the Start menu (or, in Windows 8, the Start screen), the 64-bit versions of these are listed as *Windows PowerShell* and *Windows PowerShell ISE*. The 32-bit versions are identified by an *(x86)* in the shortcut name, and you’ll also see *(x86)* in the window’s title bar when running those versions. If you’re on a 32-bit operating system, you’ll have only the 32-bit version of PowerShell, and it won’t specifically say *(x86)*.

The examples in this book are based on the 64-bit versions of PowerShell and the ISE. If you’re not using those, you may sometimes get slightly different results than ours when running examples, and a few of the labs might not work properly. The 32-bit versions are primarily provided for backward compatibility. For example, some shell extensions are available only in 32-bit flavors and can be loaded into only the 32-bit (or x86) shell. Unless you need to use such an extension, we recommend using the 64-bit shell when you’re on a 64-bit operating system. Microsoft’s investments going forward are primarily in 64-bit; if you’re stuck with a 32-bit operating system, unfortunately that’s going to hold you back.

TIP You should be able to accomplish everything in this book with a single computer running PowerShell, although some stuff gets more interesting if you have two or three computers, all in the same domain, to play with. We’ve used CloudShare (www.cloudshare.com) as an inexpensive way to spin up several virtual machines in the cloud. If such a scenario interests you, look into that service or something like it. Note that CloudShare isn’t available in all countries. Another possibility if you’re running Windows 8 or later is to use the Hyper-V feature and run a few virtual machines there.

If you’re using a non-Windows build of PowerShell, you’ll have fewer options to worry about. Just get the right build for your version of macOS or Linux (or whatever) from

<http://github.com/PowerShell/PowerShell>, and you should be good to go. Keep in mind, however, that a lot of the *functionality* we'll be using in our examples is unique to Windows. For example, you can't get a list of services on Linux, because Linux doesn't have services (it has daemons, which are similar, but different).

1.6 **Installing Windows PowerShell**

Windows PowerShell v3 has been available for most versions of Windows since the release of Windows Server 2008, Windows Server 2008 R2, Windows 7, and later versions. Windows Vista isn't supported, but it can still run v2. The shell is preinstalled only on the most recent versions of Windows; it must be manually installed on older versions. PowerShell v4 is available for Windows 7 and later and Windows Server 2008 R2 or later, although those versions of Windows don't have as many components that are "hooked up" to PowerShell, which is why we recommend Windows 8 or Windows Server 2012 as minimum versions. And although PowerShell v4 isn't the latest version of the shell, that or anything later will suffice for this book's content.

TIP You should check your version of PowerShell: Open the PowerShell console, type `$PSVersionTable`, and hit Enter. If you get an error, or if the output doesn't indicate PSVersion 4.0, then you don't have PowerShell v4.

If you want to check the latest available version of PowerShell or download it, go to <http://msdn.microsoft.com/powershell>. This official PowerShell home page has links to the latest Windows Management Framework (WMF) installer, which is what installs PowerShell and its related technologies. Again, because this book is covering entry-level stuff, you'll find that not much has changed from v3, but it's always fun to have the latest version to play with.

PowerShell has two application components: the standard, text-based console host (`PowerShell.exe`) and the more visual ISE (`PowerShell_ISE.exe`). We use the text-based console most of the time, but you're welcome to use the ISE if you prefer.

NOTE The PowerShell ISE isn't preinstalled on server operating systems. If you want to use it, you'll need to go into Windows Features (using Server Manager) and manually add the ISE feature (you can also open the PowerShell console and run `Add-WindowsFeature powershell-ise`). The ISE isn't available at all on server installations that don't have the full GUI (for example, Server Core or Nano Server).

Before you go any further, take a few minutes to customize the shell. If you're using the text-based console host, we strongly recommend that you change the default console font to the Lucida fixed-width font. The default font makes it difficult to distinguish some of the special punctuation characters that PowerShell uses. Follow these steps to customize the font:

- 1 Click the control box (that's the PowerShell icon in the upper left of the console window) and select Properties from the menu.

- 2 In the dialog box that appears, browse through the various tabs to change the font, window colors, window size and position, and so forth.

TIP We strongly recommend you make sure that both the Window Size and Screen Buffer have the same Width values.

Your changes will apply to the default console, meaning they'll stick around when you open new windows. Of course, all of this applies only to Windows: On non-Windows operating systems, you'll usually install PowerShell, open your operating system's command-line (for example, a Bash shell), and run powershell1. Your console window will determine your colors, screen layout, and so on, so adjust to suit your preferences.

1.7 **Contacting us**

We're passionate about helping folks like you learn Windows PowerShell, and we try to provide as many resources as we can. We also appreciate your feedback, because that helps us come up with ideas for new resources that we can add to the site, and ways to improve future editions of this book. You can reach Don on Twitter @concentratedDon, or Jeff @JeffHicks. We also both hang out in the forums of <http://PowerShell.org> if you have PowerShell questions. <http://PowerShell.org> is also a wonderful place for more resources, including free e-books, an in-person annual conference, free webinars, and tons more. We help run the organization, and we can't recommend it highly enough as a place to continue your PowerShell education after you've finished this book.

1.8 **Being immediately effective with PowerShell**

Immediately effective is a phrase we've made our primary goal for this entire book. As much as possible, each chapter focuses on something that you could use in a real production environment, right away. That means we sometimes gloss over some details in the beginning, but when necessary we promise to circle back and cover those details at the right time. In many cases, we had to choose between hitting you with 20 pages of theory first, or diving right in and accomplishing something without explaining all the nuances, caveats, and details. When those choices came along, we almost always chose to dive right in, with the goal of making you *immediately effective*. But all of those important details and nuances are still explained later in the book.

OK, that's enough background. It's time to start being immediately effective. Your first lunch lesson awaits.

Meet PowerShell

This chapter is all about getting you situated and helping you to decide which PowerShell interface you'll use (yes, you have a choice). If you've used PowerShell before, this material might seem redundant, so feel free to *skip* this chapter—you might still find some tidbits here and there that'll help you down the line.

Also, this chapter applies exclusively to PowerShell on Windows. Non-Windows versions don't come in as many options or flavors, so if that's your situation, you can skip this chapter.

2.1 Choose your weapon

On Windows, Microsoft provides two ways (four, if you're being picky) for you to work with PowerShell. Figure 2.1 shows the Start screen's Apps page, with four PowerShell icons. We've highlighted them to help you spot them more easily.

TIP On older versions of Windows, these icons are on your Start menu. You point to All Programs > Accessories > Windows PowerShell to find the icons. You can also select Run from the Start menu, type `powershell.exe`, and hit Enter to open the PowerShell console application. On Windows 8 and Windows Server 2012 or later, hold the Windows key on your keyboard and press R to get the Run dialog box. Or press and release the Windows key, and start typing `powershell` to quickly get to the PowerShell icons.

On a 32-bit operating system, you have only two (at most) PowerShell icons; on a 64-bit system, you have up to four. These include

- *Windows PowerShell*—64-bit console on a 64-bit system; 32-bit console on a 32-bit system
- *Windows PowerShell (x86)*—32-bit console on a 64-bit system
- *Windows PowerShell ISE*—64-bit graphical console on a 64-bit system; 32-bit graphical console on a 32-bit system
- *Windows PowerShell ISE (x86)*—32-bit graphical console on a 64-bit system

In other words, 32-bit operating systems have only 32-bit PowerShell applications, whereas 64-bit operating systems have both 64-bit and 32-bit versions, and the 32-bit versions include *x86* in their icon names. You'd use the 32-bit versions only when you have a 32-bit shell extension for which a 64-bit version isn't available. Microsoft is fully invested in 64-bit these days, and it maintains the 32-bit versions mainly for backward compatibility.

TIP It's incredibly easy to accidentally launch the wrong application when you're on a 64-bit operating system. Get in the habit of looking at the application window's title bar: If it shows *x86*, you're running a 32-bit application. The 64-bit extensions (and most new ones are 64-bit) won't be available in a 32-bit application. Our recommendation is to pin a shortcut to your shell of choice to the Start menu.

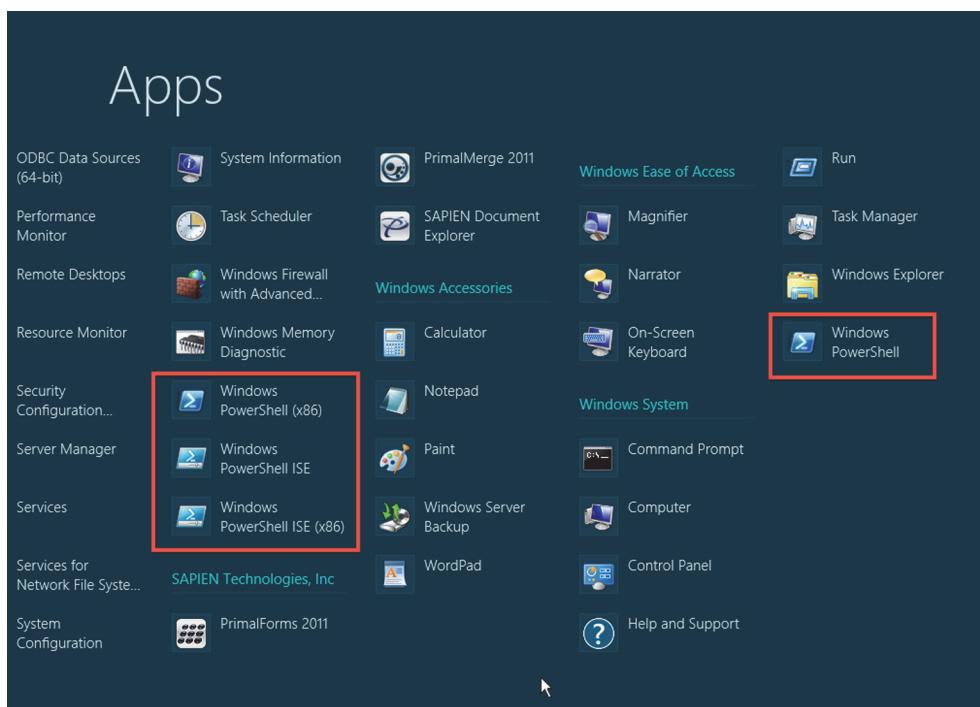

Figure 2.1 You can run PowerShell in one of four possible ways.

2.1.1 The console window

Figure 2.2 shows the console window, which is where most folks first meet PowerShell. We'll start this section by making some arguments against using the PowerShell console application:

- It doesn't support double-byte character sets, which means many non-English languages won't display properly.
- Clipboard operations (copy and paste) use nonstandard keystrokes that are hard to get used to.
- It provides little assistance when it comes to typing (compared to the ISE, which we cover next), although in PowerShell v5 it's gotten a lot better. In Windows 10, Microsoft revised the command shell, fixing some of the long-standing issues we mentioned, so your experience could be slightly different.

That said, the PowerShell console application is your only option when you're running PowerShell on a server that doesn't have a GUI shell installed (that's any Server

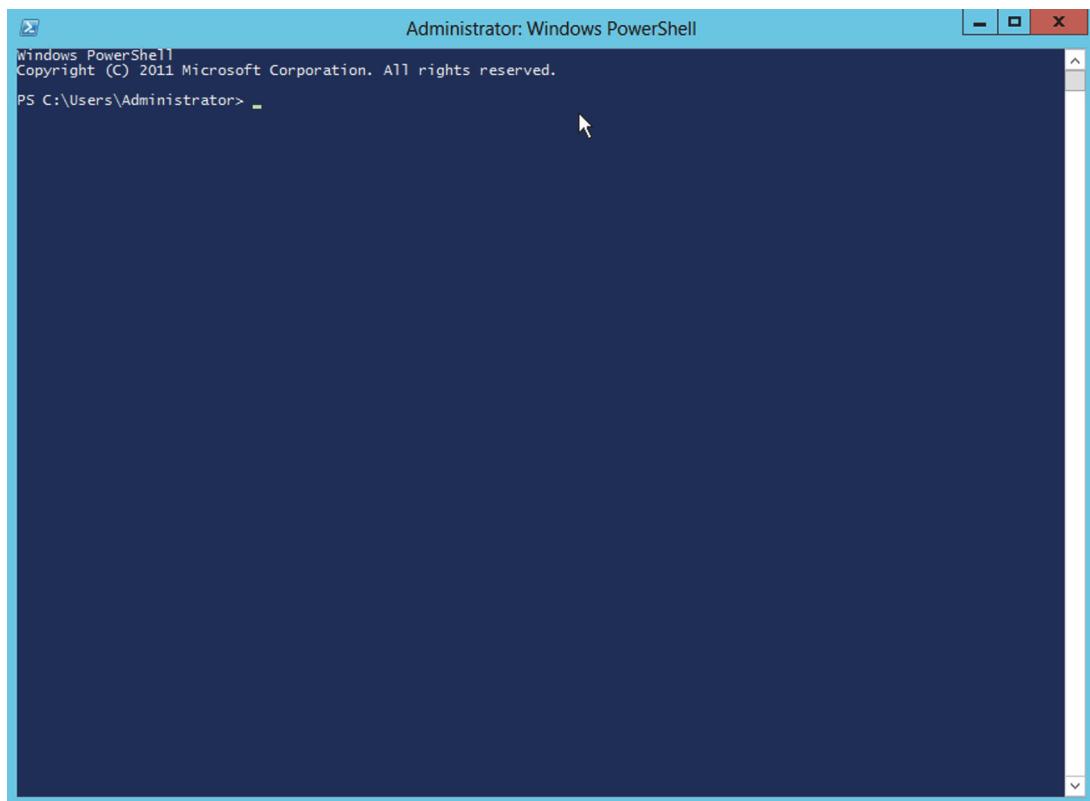

Figure 2.2 The standard PowerShell console window: `PowerShell.exe`

Core installation, Nano Server, or any Windows Server installation on which the Server GUI Shell feature has been removed or not installed). On the plus side

- The console application is tiny. It loads fast and doesn't use much memory.
- It doesn't require any more .NET Framework stuff than PowerShell itself needs.
- You can set the colors to be green text on a black background and pretend you're working on a 1970s-era mainframe.

If you decide to use the console application, we have a few suggestions for configuring it. You can make all of these configurations by clicking the window's upper-left-corner control box and selecting Properties; you'll see the dialog box in figure 2.3. This looks slightly different in Windows 10, as it's gained some new options, but the gist is the same.

On the Options tab, you can increase the size of the Command History Buffer Size. This buffer enables the console to remember which commands you've typed, and lets you recall them by using the up and down arrows on your keyboard. You can also hit F7 for a pop-up list of commands.

On the Font tab, pick something a bit larger than the default 12 pt font. Please. We don't care if you have 20/10 vision; jack up the font size a bit. PowerShell needs you to be able to quickly distinguish between a lot of similar-looking characters—such as ' (an

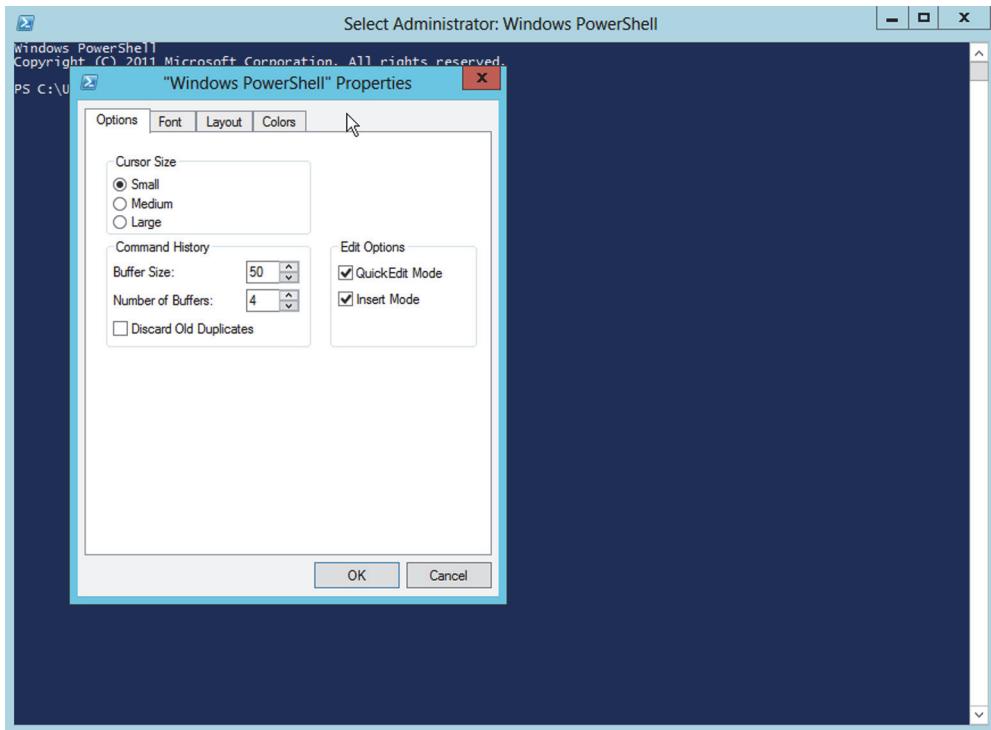

Figure 2.3 Configuring the console application's properties

apostrophe or a single quote) and ` (a backtick or a grave accent)—and a tiny font doesn’t help.

On the Layout tab, set both Width sizes to the same number, and make sure the resulting window fits on your screen. Failing to do this can result in a horizontal scrollbar at the bottom of the window, which can lead to some PowerShell output appearing wrapped off the right side of the window, where you’ll never see it. We’ve had students spend half an hour running commands, thinking they were producing no output at all, when in fact the output was scrolled off to the right. Annoying.

Finally, on the Colors tab, don’t go nuts. Keep things high contrast and easy to read. Black on medium-gray is quite nice if you don’t like the default white on blue.

One point to keep in mind: This console application isn’t PowerShell; it’s merely the means by which you interact with PowerShell. The console app itself dates to circa 1985. It’s primitive, and you shouldn’t expect to have a slick experience with it.

2.1.2 The Integrated Scripting Environment

Figure 2.4 shows the PowerShell Integrated Scripting Environment, or ISE.

TIP If you accidentally open the standard console app, you can type ise and hit Enter to open the ISE.

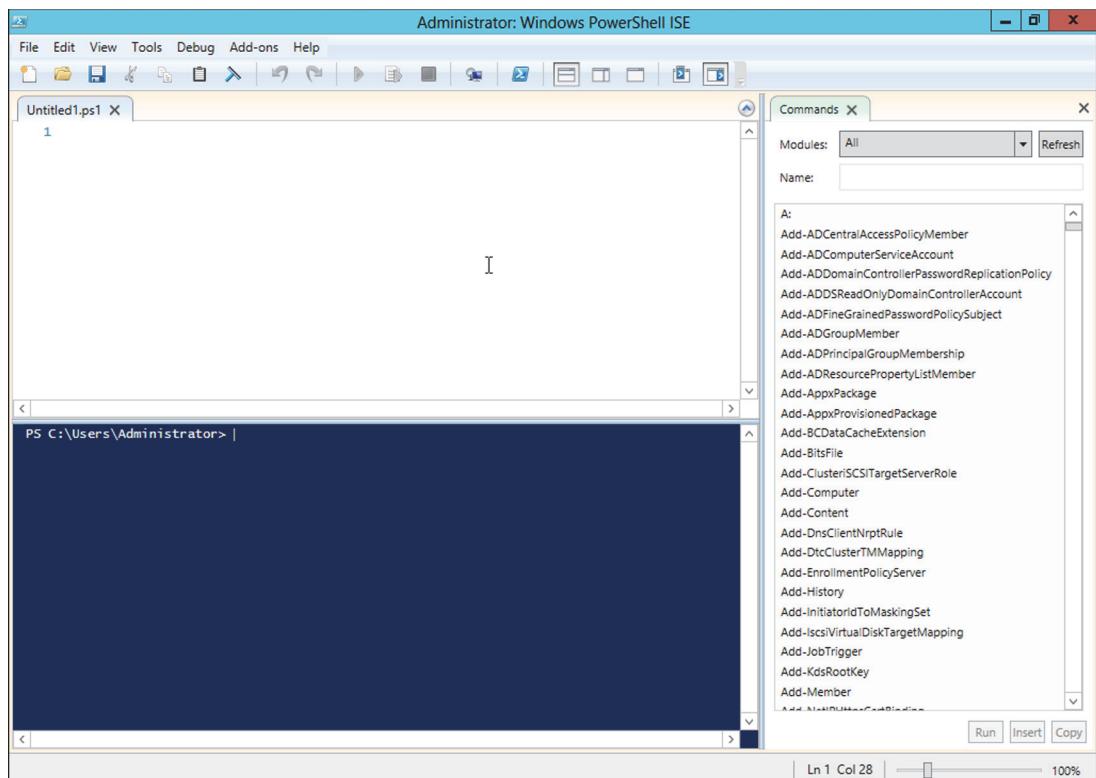

Figure 2.4 The PowerShell ISE (PowerShell_ISE.exe)

We have a lot of ground to cover with the ISE, and we'll start with table 2.1, which lists its pros and cons.

Table 2.1 ISE pros and cons

Pros	Cons
ISE is nicer looking and supports double-byte character sets.	It requires Windows Presentation Foundation (WPF), which means it can't run on a server that's had the GUI uninstalled (although it can run in Minimal Server GUI mode, which supports WPF applications).
It does more to help you create PowerShell commands and scripts, as you'll see later in this chapter.	It takes longer to get up and running, but usually only a couple of seconds longer.
It uses standard copy-and-paste keystrokes.	It doesn't support transcription in versions prior to 5.0.

Let's start with basic orientation. Figure 2.5 labels the ISE's three main areas, and we've highlighted the area of the ISE toolbar that controls these main areas.

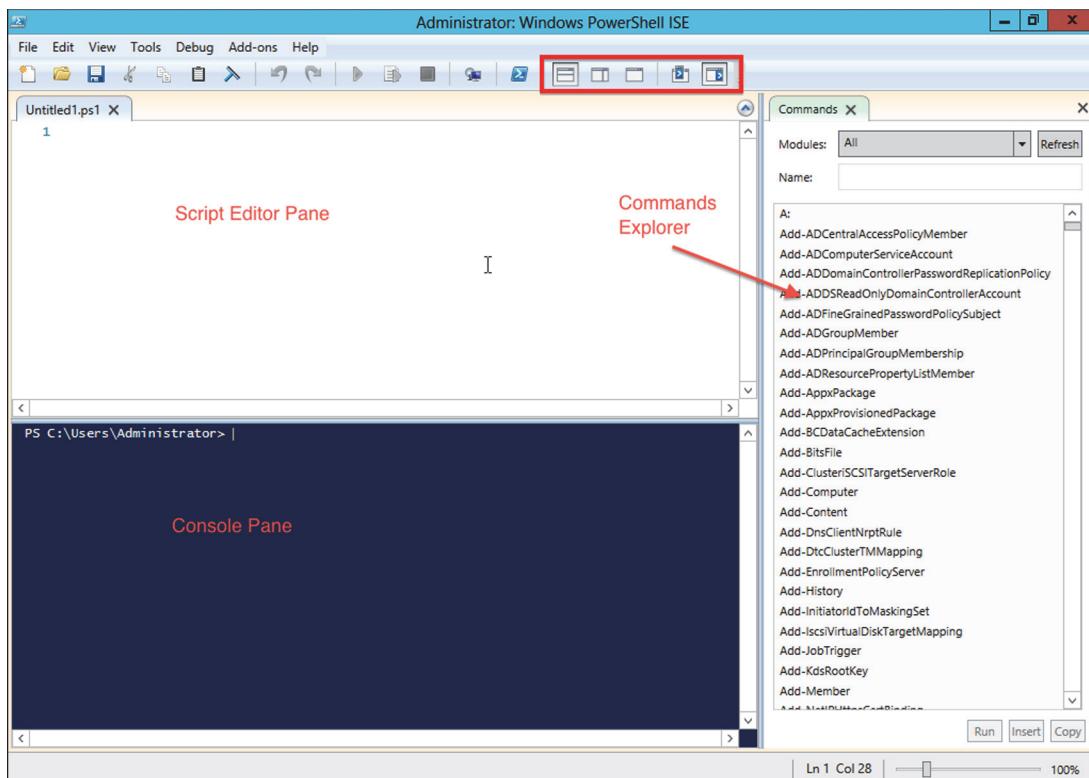

Figure 2.5 The three main areas of the ISE, and the toolbar that controls them

In figure 2.5, the top area is the Script Editor pane, which we won't be using until the end of this book. In the upper-right corner of that pane, you'll notice a little blue arrow; click it to hide the Script Editor and maximize the Console pane, which is the area we'll be using. On the right side is the Commands Explorer, which you can leave open or close by using the little X in its upper-right corner. You can also float the Commands Explorer by clicking the next-to-last button in the toolbar. If you close the Commands Explorer and want it back, the last button in the toolbar will bring it back. The first three buttons we've highlighted in the toolbar control the layout of the Script Editor and Console panes. You can set these panes one above the other, side by side, or as a full-screen Script Editor pane.

In the lower-right corner of the ISE window, you'll find a slider that changes the font size. On the Tools menu, an Options item lets you configure custom color schemes and other appearance settings; feel free to play with those.

TRY IT NOW We'll assume you're using the ISE for the remainder of this book and not some other scripting editor when you need to write or examine a script. For now, hide the Script Editor pane and (if you want to) the Commands Explorer. Set the font size to something you like. If the default color scheme isn't to your liking, change it to something you prefer. If you decide to use the console window instead, you'll be fine—most everything in the book will still work. For the few ISE-specific things we'll show you, we'll be sure to tell you that it works only in the ISE, to give you a chance to switch.

2.2 It's typing class all over again

PowerShell is a command-line interface, and that means you'll do a lot of typing. Typing leaves room for errors—typos. Fortunately, both PowerShell applications provide ways to help minimize typos.

TRY IT NOW The following examples are impossible to illustrate in a book, but they're cool to see in action. Consider following along in your own copy of the shell.

The console application supports Tab completion in four areas:

- Type `Get-S` and press Tab a few times, and then try pressing Shift-Tab. PowerShell cycles back and forth through all of the potential matches. Continue to press those keys until you've hit the command you want.
- Type `Dir`, then a space, then `C:\`, and then hit Tab. PowerShell starts cycling through available file and folder names from the current folder.
- Type `Set-Execu` and hit Tab. Then type a space and a hyphen (-). Start pressing Tab to see PowerShell cycle through the parameters for the command. You could also type part of a parameter name (for example, `-E`), and press Tab to start cycling through matching parameters. Hit Esc to clear the command line.
- Type `Set-Execu` again and press Tab. Type a space, then `-E`, and hit Tab again. Type another space and hit Tab again. PowerShell cycles through the legal values

for that parameter. This works only for parameters that have a predefined set of allowable values (the set is called an *enumeration*). Again, hit Esc to clear the command line; you don't want to run that command yet.

The PowerShell ISE offers something similar to, and better than, Tab completion: IntelliSense. This feature operates in all four of the same situations that we showed you for Tab completion, except that you get a cool little pop-up menu, like the one shown in figure 2.6. You can use your arrow keys to scroll up or down, find the item you want, hit Tab or Enter to select it, and then keep typing.

IntelliSense works in the ISE's Console pane and in the Script Editor pane.

CAUTION It's *very, very, very, very, very* important to be *very, very, very, very* accurate when you're typing in PowerShell. In some cases, a single misplaced space, quotation mark, or even carriage return can make everything fail. If you're getting errors, double- and triple-check what you've typed.

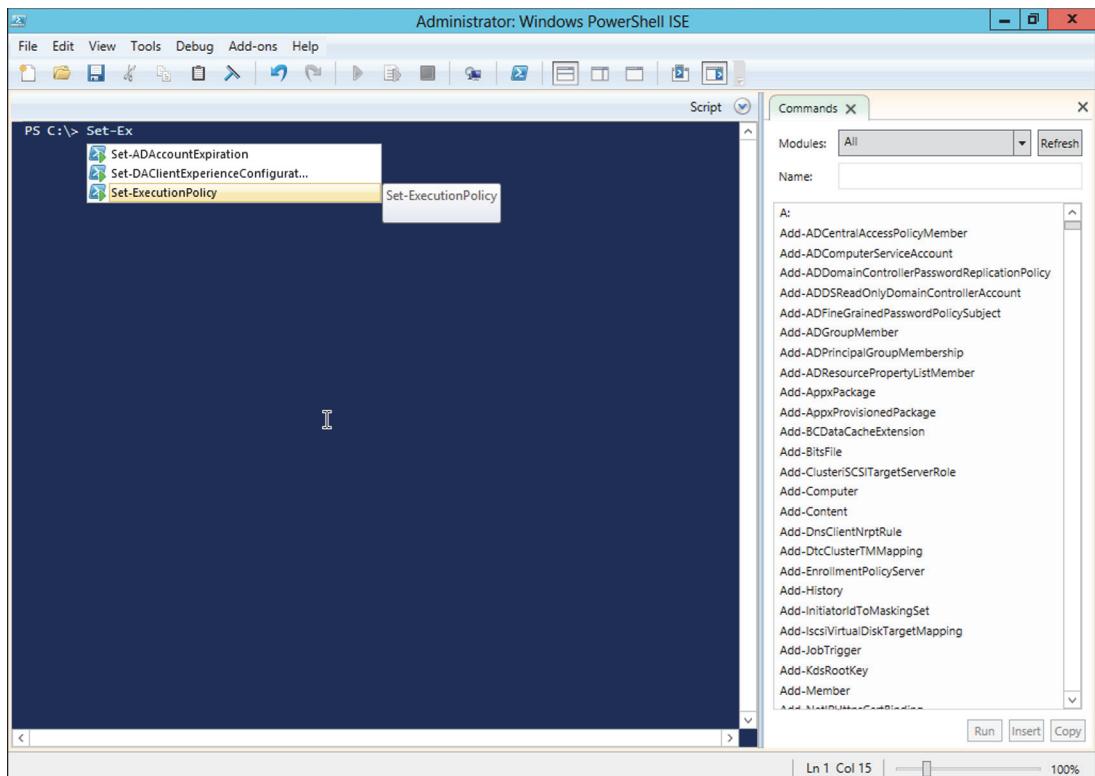

Figure 2.6 IntelliSense works like Tab completion in the ISE.

2.3 Common points of confusion

Let's quickly review some of the things that can muck up the works, to make sure they don't trip you up:

- *Horizontal scrollbars in the console app*—We've learned from years of teaching classes that this trips up people every single time. Configure the console to not have a horizontal scrollbar across the bottom of the window. We explained how to do this earlier in this chapter.
- *The 32-bit versus 64-bit issue*—You should be running a 64-bit version of Windows and using the 64-bit versions of PowerShell's applications—the ones that don't indicate (*x86*). We know for some folks it can be a big deal to go buy a 64-bit computer and a 64-bit version of Windows. But that's the investment you'll have to make if you want to use PowerShell effectively. Most of what we cover in this book will work fine on 32-bit, but when you're working in a production environment, 64-bit makes all the difference.
- *Make sure the PowerShell application window's title bar reads "Administrator"*—If it doesn't, close the window, right-click the PowerShell icon again, and select Run As Administrator. In a production environment, you might not always do this, and later in the book we'll show you how to specify credentials when you run commands. But for the moment, you need to be sure the shell window reads *Administrator*, or you'll run into problems later.

2.4 What version is this?

It can be incredibly difficult to figure out which version of PowerShell you're using, in no small part because every released version installs to a directory named *1.0*. (This refers to the language engine of the shell, meaning every version has been made backward compatible to v1.) With PowerShell v3 and later, there's an easy way to check your version. Type `$PSVersionTable` and hit Enter:

```
PS C:\> $PSVersionTable
Name                Value
----              -----
PSVersion          3.0
WSManStackVersion 3.0
SerializationVersion 1.1.0.1
CLRVersion         4.0.30319.17379
BuildVersion        6.2.8250.0
PSCompatibleVersions {1.0, 2.0, 3.0}
PSRemotingProtocolVersion 2.2
```

You'll immediately see the version number for every PowerShell-related piece of technology, including PowerShell itself. If this doesn't work, or if it doesn't indicate *3.0* or later for *PSVersion*, you're not using the right version of PowerShell for this book. Refer to chapter 1 for instructions on getting the most current version of PowerShell.

TRY IT NOW Don't wait any longer to start using PowerShell. Start by checking your version number to ensure it's at least 3.0. If it isn't, don't go any further until you've installed at least v3.

PowerShell v3 (and later) can install side-by-side with v2. In fact, you can run `PowerShell.exe -version 2.0` to explicitly run v2. You can set PowerShell to run v2 if you have something that isn't v3 compatible (which is rare). PowerShell v3's installer doesn't install v2; you'll be able to run v2 only if it was installed first. The installers for v2 and v3 will both overwrite v1 if it's already installed; they can't exist side by side. Also, newer versions such as v4 can run in v2 mode, but they don't have any other modes. So, v4 can't run as v3.

TIP New versions of Windows install the latest version of PowerShell by default, but may include the PowerShell v2 engine. From PowerShell, you can usually run `Add-WindowsFeature powershell-v2` to install the v2 engine if you need it. If the `powershell-v2` feature isn't available on your version of Windows, then you're out of luck for installing it, but at this point you may not need it.

2.5 Lab

Because this is the book's first lab, we'll take a moment to describe how these are supposed to work. For each lab, we give you a few tasks that you can try to complete on your own. Sometimes we provide a hint or two to get you going in the right direction. From there, you're on your own.

We absolutely guarantee that everything you need to know to complete every lab is either in that same chapter or covered in a previous chapter (and the previously covered information is the stuff for which we're most likely to give you a hint). We're not saying the answer is in plain sight: Most often, a chapter teaches you how to discover something on your own, and you have to go through that discovery process to find the answer. It might seem frustrating, but forcing yourself to do it will absolutely make you more successful with PowerShell in the long run. We promise.

Keep in mind that you can find sample answers at the end of each chapter. Our answers might not exactly match yours, and that will become increasingly true as we move on to more complex material. You'll often find that PowerShell offers a half dozen or more ways to accomplish almost anything. We'll show you the way we use the most, but if you come up with something different, you're not wrong. Any way that gets the job done is correct.

NOTE For this lab, you need any computer running PowerShell v3 or later.

We'll start easy: We just want you to get both the console and the ISE set up to meet your needs. Follow these five steps:

- 1 Select fonts and colors that work for you.
- 2 Make sure the console application has no horizontal scrollbar at the bottom. We've now mentioned this three times in this chapter, so maybe it's important.
- 3 In the ISE, maximize the Console pane; remove or leave the Commands Explorer at your discretion.
- 4 In both applications, type a single quote, ', and a backtick, ` , and make sure you can easily tell the difference. On a U.S. keyboard (at least), a backtick is on one of the upper-left keys, under the Esc key, on the same key as the tilde (~) character.
- 5 Also type (parentheses), [square brackets], <angle brackets>, and {curly brackets} to make sure the font and size you've selected display well, so that all of these symbols are immediately distinguishable. If there's some visual confusion about which is which, change fonts or select a bigger font size.

We've already walked you through how to accomplish these steps, so you don't have any answers to check for this lab, other than to be sure you've completed all five of the steps.

Using the help system

In the first chapter of this book, we mentioned that discoverability is a key feature that makes graphical user interfaces (GUIs) easier to learn and use, and that command-line interfaces (CLIs) like PowerShell are often more difficult because they lack those discoverability features. In fact, PowerShell has fantastic discoverability features—but they’re not that obvious. One of the main discoverability features is its help system.

3.1 **The help system: how you discover commands**

Bear with us for a minute as we climb up on a soapbox and preach to you.

We work in an industry that doesn’t place a lot of emphasis on reading, although we do have an acronym, *RTFM*, that we cleverly pass along to users when we wish *they* would *read the friendly manual*. Most administrators tend to dive right in, relying on things like tooltips, context menus, and so forth—those *GUI* discoverability tools—to figure out how to do something. That’s how we often work, and we imagine you do the same thing. But let’s be clear about one point:

If you aren’t willing to read PowerShell’s help files, you won’t be effective with PowerShell. You won’t learn how to use it, you won’t learn how to administer products like Windows with it, and you might as well stick with the GUI.

That’s about as clear as we can be. It’s a blunt statement, but it’s absolutely true. Imagine trying to figure out Active Directory Users and Computers, or any other administrative console, without the help of tooltips, menus, and context menus. Trying to learn to use PowerShell without taking the time to read and understand the help files is the same thing. It’s like trying to assemble that do-it-yourself furniture

from the department store without reading the manual. Your experience will be frustrating, confusing, and ineffective. Why?

- If you need to perform a task and don't know what command to use, the help system is how you'll find that command. Not Google or Bing, but the help system.
- If you run a command and get an error, the help system is what will show you how to properly run the command so you don't get errors.
- If you want to link multiple commands together to perform a complex task, the help system is where you'll find out how each command is able to connect to others. You don't need to search for examples on Google or Bing; you need to learn how to use the commands themselves so that you can create your own examples and solutions.

We realize our preaching is a little heavy-handed, but 90% of the problems we see students struggling with in class, and on the job, could be solved if those folks would find a few minutes to sit back, take some deep breaths, and read the help. And then read this chapter, which is all about helping you understand the help you're reading in PowerShell.

From here on out, we encourage you to read the help for several reasons:

- Although we show many commands in our examples, we almost never expose the complete functionality, options, and capabilities of each command. You should read the help for each and every command we show you, so that you'll be familiar with the additional actions each command can accomplish.
- In the labs, we may give you a hint about which command to use for a task, but we won't give you hints about the syntax. You'll need to use the help system to discover that syntax on your own in order to complete the labs.

We promise you that mastering the help system is the key to becoming a PowerShell expert. No, you won't find every little detail in there, and a lot of super-advanced material isn't documented in the help system, but in terms of being an effective day-to-day administrator, you need to master the help system. This book will make that system understandable, and it will teach you the concepts that the help skips over, but it'll do this only in conjunction with the built-in help.

Stepping off the soapbox now.

Command vs. cmdlet

PowerShell contains many types of executable commands. Some are called *cmdlets*, some are called *functions*, others are known as *workflows*, and so on. Collectively, they're all *commands*, and the help system works with all of them. A *cmdlet* is something unique to PowerShell, and many of the commands you run will be cmdlets. But we'll try to consistently use *command* whenever we're talking about the more general class of executable utility.

3.2 Updatable help

You may be surprised the first time you fire up help in PowerShell, because, well, there isn't any. But wait, we can explain.

Microsoft included a new feature beginning with PowerShell v3 called *updatable help*. PowerShell can download updated, corrected, and expanded help right from the internet. Unfortunately, in order to do that, Microsoft can't ship any help "in the box." When you ask for help on a command, you get an abbreviated, autogenerated version of help, along with a message on how to update the help files, which may look like the following:

```
PS C:\> help Get-Service
NAME
    Get-Service
SYNTAX
    Get-S          -- To view the Help topic for this cmdlet online, type:
        "Get-Help
    ervice [[-Name] <string[]>] [-ComputerName <string[]>]
        [-DependentServices] [-RequiredServices] [-Include <string[]>]
        [-Exclude <string[]>] [<CommonParameters>]
    Get-Service -DisplayName <string[]> [-ComputerName <string[]>]
        [-DependentServices] [-RequiredServices] [-Include <string[]>]
        [-Exclude <string[]>] [<CommonParameters>]
    Get-Service [-ComputerName <string[]>] [-DependentServices]
        [-RequiredServices] [-Include <string[]>] [-Exclude <string[]>]
        [-InputObject <ServiceController[]>] [<CommonParameters>]
ALIASES
    gsv
REMARKS
    Get-Help cannot find the Help files for this cmdlet on this computer.
    It is displaying only partial help.
        -- To download and install Help files for the module that
        includes this cmdlet, use Update-Help.
    Get-Service -Online" or
        go to http://go.microsoft.com/fwlink/?LinkID=113332.
```

TIP It's impossible to miss the fact that you don't have local help installed. The first time you ask for help, PowerShell will prompt you to update the help content.

Updating PowerShell's help should be your first task. These files are stored in the System32 directory, which means your shell must be running under elevated privileges. If the PowerShell title bar doesn't show *Administrator*, you'll likely get an error message:

```
PS C:\> update-help
Update-Help : Failed to update Help for the module(s)
'Microsoft.PowerShell.Management', 'Microsoft.PowerShell.Utility',
'Microsoft.PowerShell.Diagnostics', 'Microsoft.PowerShell.Core',
'Microsoft.PowerShell.Host', 'Microsoft.PowerShell.Security',
'Microsoft.WSMAN.Management' : This command did not update help topics for
the Windows PowerShell core commands or for any modules in the
$pshome\Modules directory. To update these help topics, start Windows
```

```
PowerShell with the "Run as Administrator" option and try the command
again.
At line:1 char:1
+ update-help
+ ~~~~~
+ CategoryInfo          : InvalidOperation: (:) [Update-Help], Except
ion
+ FullyQualifiedErrorId : UpdatableHelpSystemRequiresElevation,Micros
oft.PowerShell.Commands.UpdateHelpCommand
```

We've boldfaced the important part of the preceding error message; it tells you what the problem is and how to solve it. Run the shell as administrator, run `Update-Help` again, and you'll be good to go in a few minutes.

It's important to get in the habit of updating the help every month or so. PowerShell can even download updated help for non-Microsoft commands, provided the commands' modules are located in the proper spot and that they've been coded to include the online location for updated help.

Do you have computers that aren't connected to the internet? No problem: Go to one that's connected, and use `Save-Help` to get a local copy of the help. Put it on a file server or somewhere that's accessible to the rest of your network. Then run `Update-Help` with its `-Source` parameter, pointing it to the downloaded copy of the help. That'll let any computer on your network grab the updated help from that central spot, rather than from the internet.

Help is open sourced

Microsoft's PowerShell help files are open source materials that are available at <http://github.com/powershell>. That can be a good place to see the latest source, which might not yet be compiled into help files that PowerShell can download and display.

3.3 Asking for help

PowerShell provides a cmdlet, `Get-Help`, that accesses the help system. You may see examples (especially on the internet) that show people using the `Help` keyword instead or even the `Man` keyword (which comes from UNIX and means *Manual*). `Man` and `Help` aren't native cmdlets at all; they're *functions*, which are wrappers around the core `Get-Help` cmdlet.

Help on macOS/Linux

The help files, when viewed on macOS and Linux, are displayed using the operating system's traditional *man* (manual) feature, which usually "takes over" the screen to display the help, returning you to your normal screen when you're finished.

Help works much like the base Get-Help, but it pipes the help output to More, allowing you to have a nice paged view instead of seeing all the help fly by at once. Running Help Get-Content and Get-Help Get-Content produces the same results, but the former has a page-at-a-time display. You could run Get-Help Get-Content | More to produce that paged display, but that requires a lot more typing. We typically use only Help, but we want you to understand that some trickery is going on under the hood.

NOTE Technically, Help is a function, and Man is an alias, or nickname, for Help. But you get the same results using either. We discuss aliases in the next chapter.

By the way, sometimes that paginated display can be annoying, because you have the information you need, but it still wants you to hit the spacebar to display the remaining information. If you encounter this, press Ctrl-C to cancel the command and return to the shell prompt. Within the shell's console window, Ctrl-C always means *break* rather than *copy to the clipboard*. But in the more graphically oriented Windows PowerShell ISE, Ctrl-C does copy to the clipboard. A red Stop button in the toolbar will stop a running command.

NOTE The More command won't work in the ISE. Even if you use Help or Man, the help content displays all at once rather than a page at a time.

The help system has two main goals: to help you find commands to perform specific tasks, and to help you learn how to use those commands after you've found them.

3.4 Using help to find commands

Technically speaking, the help system has no idea what commands are present in the shell. All it knows is what help topics are available, and it's possible for commands to not have a help file, in which case the help system won't know that the commands exist. Fortunately, Microsoft ships a help topic for nearly every cmdlet it produces, which means you usually won't find a difference. In addition, the help system can access information that isn't related to a specific cmdlet, including background concepts and other general information.

Like most commands, Get-Help (and therefore Help) has several parameters. One of those—perhaps the most important one—is -Name. This parameter specifies the name of the help topic you'd like to access, and it's a positional parameter, so you don't have to type -Name; you can just provide the name you're looking for. It also accepts wildcards, which makes the help system useful for discovering commands.

For example, suppose you want to do something with an event log. You don't know what commands might be available, and you decide to search for help topics that cover event logs. You might run either of these two commands:

```
Help *log*
Help *event*
```

The first command returns a list like the following on your computer:

Name	Category	Module
Clear-EventLog	Cmdlet	Microsoft.PowerShell.M...
Get-EventLog	Cmdlet	Microsoft.PowerShell.M...
Limit-EventLog	Cmdlet	Microsoft.PowerShell.M...
New-EventLog	Cmdlet	Microsoft.PowerShell.M...
Remove-EventLog	Cmdlet	Microsoft.PowerShell.M...
Show-EventLog	Cmdlet	Microsoft.PowerShell.M...
Write-EventLog	Cmdlet	Microsoft.PowerShell.M...
Get-AppxLog	Function	Appx
Get-DtcLog	Function	MsDtc
Reset-DtcLog	Function	MsDtc
Set-DtcLog	Function	MsDtc
Get-LogProperties	Function	PSDiagnostics
Set-LogProperties	Function	PSDiagnostics
about_Eventlogs	HelpFile	
about_Logical_Operators	HelpFile	

NOTE You'll notice that the preceding list includes commands (and functions) from modules such as Appx and MsDtc. The help system displays all of these even though you haven't loaded those extensions into memory yet, which helps you discover commands on your computer that you might otherwise have overlooked. It'll discover commands from any extensions that are installed in the proper location, which we discuss in chapter 7.

Many of the functions in the previous list seem to have something to do with event logs, and based on a verb-noun naming format, all but the last two appear to be help topics related to specific cmdlets. The last two about topics provide background information. The last one doesn't seem to have anything to do with event logs, but it came up because it does have Log in it—part of the word Logical. Whenever possible, try to search using the broadest term possible—*event* or *log* as opposed to *event-log*—because you'll get the most results possible.

When you have a cmdlet that you think will do the job (`Get-EventLog` looks like a good candidate for what you're after in the example), you can ask for help on that specific topic:

```
Help Get-EventLog
```

Don't forget about Tab completion! As a reminder, it lets you type a portion of a command name and press Tab, to have the shell complete what you've typed with the closest match. You can continue pressing Tab to cycle through alternative matches.

TRY IT NOW Type `Help Get-Ev` and press Tab. The first match is `Get-Event`, which isn't what you want; pressing Tab again brings up `Get-EventLog`, which is what you're after. You can hit Enter to accept the command and display the help for that cmdlet. If you're using the ISE, you don't even have to hit Tab; the list of matching commands pops right up, and you can select one and hit Enter to finish typing it.

You can also use wildcards—mainly the `*` wildcard, which stands in for zero or more characters—with `Help`. If PowerShell finds only one match to whatever you’ve typed, it won’t display a list of topics for that one item. Instead, it’ll display the content for that item.

TRY IT NOW Run `Help Get-EventLog*` and you should see the help file for `Get-EventLog`, rather than a list of matching help topics.

If you’ve been following along in the shell, you should now be looking at the help file for `Get-EventLog`. This file, called the *summary help*, is meant to be a short description of the command and a reminder of the syntax. This information is useful when you need to quickly refresh your memory of a command’s usage, and it’s where we’ll begin interpreting the help file itself.

Above and beyond

Sometimes we want to share information that, although nice, isn’t essential to your understanding of the shell. We put that information into an “Above and beyond” section, like this one. If you skip these, you’ll be fine; if you read them, you’ll often learn about an alternative way of doing something or get additional insight into PowerShell.

We mentioned that the `Help` command doesn’t search for cmdlets; it searches for help topics. Because every cmdlet has a help file, we could say that this search retrieves the same results. But you can also directly search for cmdlets by using the `Get-Command` cmdlet (or its alias, `Gcm`).

Like the `Help` cmdlet, `Get-Command` accepts wildcards—so you can, for example, run `Gcm *event*` to see all of the commands that contain `event` in their name. For better or worse, that list will include not only cmdlets, but also external commands such as `netevent.dll`, which may not be useful.

A better approach is to use the `-Noun` or `-Verb` parameters. Because only cmdlet names have nouns and verbs, the results will be limited to cmdlets. `Get-Command -noun *event*` returns a list of cmdlets dealing with events; `Get-Command -verb Get` returns all cmdlets capable of retrieving things. You can also use the `- CommandType` parameter, specifying a type of cmdlet: `Get-Command *log* -type cmdlet` shows a list of all cmdlets that include `log` in their names, and the list won’t include any external applications or commands.

3.5 Interpreting the help

PowerShell’s cmdlet help files have a particular set of conventions. Learning to understand what you’re looking at is the key to extracting the maximum amount of information from these files, and to learning to use the cmdlets themselves more effectively.

3.5.1 Parameter sets and common parameters

Most commands can work in a variety of ways, depending on what you need them to do. For example, here’s the syntax section for the `Get-EventLog` help:

SYNTAX

```
Get-EventLog [-AsString] [-ComputerName <string[]>] [-List] [<CommonParameters>]

Get-EventLog [-LogName] <string> [[-InstanceId] <Int64[]>] [-After <DateTime>] [-AsBaseObject] [-Before <DateTime>] [-ComputerName <string[]>] [-EntryType <string[]>] [-Index <Int32[]>] [-Message <string>] [-Newest <int>] [-Source <string[]>] [-UserName <string[]>] [<CommonParameters>]
```

Notice that the command in the previous syntax is listed twice, which indicates that the command supports two *parameter sets*; you can use the command in two distinct ways. Some of the parameters will be shared between the two sets. You'll notice, for example, that both parameter sets include a `-ComputerName` parameter. But the two parameter sets will always have at least one unique parameter that exists only in that parameter set. In this case, the first set supports `-AsString` and `-List`, neither of which is included in the second set; the second set contains numerous parameters that aren't included in the first.

Here's how this works: If you use a parameter that's included in only one set, you're locked into that set and can use only additional parameters that appear within that same set. If you choose to use `-List`, the only other parameters you can use are `-AsString` and `-ComputerName`, because those are the only two other parameters included in the parameter set where `-List` lives. You couldn't add in the `-LogName` parameter, because it doesn't live in the first parameter set. That means `-List` and `-LogName` are *mutually exclusive*. You'll never use both of them at the same time because they live in different parameter sets.

Sometimes it's possible to run a command with only parameters that are shared between multiple sets. In those cases, the shell will usually select the first-listed parameter set. Because each parameter set implies different behavior, it's important to understand which parameter set you're running.

You'll notice that every parameter set for every PowerShell cmdlet ends with `[<CommonParameters>]`. This refers to a set of eight parameters that are available on every single cmdlet, no matter how you're using that cmdlet. We won't discuss those common parameters now, but we'll discuss some of them later in this book, when we'll use them for a real task. Later in this chapter, though, we'll show you where to learn more about those common parameters, if you're interested.

NOTE Astute readers will by now have recognized variations in some of our examples. Readers will notice a different help layout for `Get-EventLog` depending on their version of PowerShell. You might even see a few new parameters. But the fundamentals and concepts we're explaining haven't changed. Don't get hung up on the fact that the help you see might be different from what we show in the book.

3.5.2 Optional and mandatory parameters

You don't need every single parameter in order to make a cmdlet run. PowerShell's help lists optional parameters in square brackets. For example, `[-ComputerName <string []>]` indicates that the entire `-ComputerName` parameter is optional. You don't have to use it at all; the cmdlet will probably default to the local computer if you don't specify an alternative name using this parameter. That's also why `[<-Common-Parameters>]` is in square brackets: You can run the command without using any of the common parameters.

Almost every cmdlet has at least one optional parameter. You may never need to use some of these parameters and may use others on a daily basis. Keep in mind that when you choose to use a parameter, you have to type only enough of the parameter name so that PowerShell can unambiguously figure out which parameter you meant. `-L` wouldn't be sufficient for `-List`, for example, because `-L` could also mean `-LogName`. But `-Li` would be a legal abbreviation for `-List`, because no other parameter starts with `-Li`.

What if you try to run a command and forget one of the mandatory parameters? Take a look at the help for `Get-EventLog`, for example, and you'll see that the `-LogName` parameter is mandatory; the parameter isn't enclosed in square brackets. Try running `Get-EventLog` without specifying a log name.

TRY IT NOW Follow along in this example by running `Get-EventLog` without any parameters.

PowerShell should have prompted you for the mandatory `LogName` parameter. If you type something like `System` or `Application` and hit Enter, the command will run correctly. You could also press Ctrl-C to abort the command.

3.5.3 Positional parameters

PowerShell's designers knew that some parameters would be used so frequently that you wouldn't want to continually type the parameter names. Those commonly used parameters are often *positional*: You can provide a value without typing the parameter's name, provided you put that value in the correct position.

You can identify positional parameters in two ways: via the syntax summary or the full help.

FINDING POSITIONAL PARAMETERS IN THE SYNTAX SUMMARY

You'll find the first way in the syntax summary: the parameter name—only the name—will be surrounded by square brackets. For example, look at the first two parameters in the second parameter set of `Get-EventLog`:

```
[-LogName] <string> [[-InstanceId] <Int64 []>]
```

The first parameter, `-LogName`, isn't optional. You can tell because the entire parameter—its name and its value—are't surrounded by square brackets. But the parameter name is enclosed in square brackets, making it a positional parameter—you could

provide the log name without having to type `-LogName`. And because this parameter appears in the first position within the help file, you know that the log name is the first parameter you have to provide.

The second parameter, `-InstanceId`, is optional; both it and its value are enclosed in square brackets. Within those, `-InstanceId` itself is also contained in square brackets, indicating that this is also a positional parameter. It appears in the second position, so you'd need to provide a value in the second position if you chose to omit the parameter name.

The `-Before` parameter (which comes later in the syntax; run `Help Get-EventLog` and find it for yourself) is optional, because it's entirely enclosed within square brackets. The `-Before` name isn't in square brackets, which tells you that if you choose to use that parameter, you must type the parameter name (or at least a portion of it).

There are some tricks to using positional parameters:

- It's OK to mix and match positional parameters with those that require their names. Positional parameters must always be in the correct positions. For example, `Get-EventLog System -Newest 20` is legal; `System` will be fed to the `-LogName` parameter because that value is in the first position, and `20` will go with the `-Newest` parameter because the parameter name was used.
- It's always legal to specify parameter names, and when you do so, the order in which you type them isn't important. `Get-EventLog -newest 20 -Log -Application` is legal because we've used parameter names (in the case of `-LogName`, we abbreviated it).
- If you use multiple positional parameters, don't lose track of their positions. `Get-EventLog Application 0` will work, with `Application` being attached to `-LogName` and `0` being attached to `-InstanceId`. `Get-EventLog 0 Application` won't work, because `0` will be attached to `-LogName`, and no log is named `0`.

We'll offer a best practice: Use parameter names until you become comfortable with a particular cmdlet and get tired of typing a commonly used parameter name over and over. After that, use positional parameters to save yourself typing. When the time comes to paste a command into a text file for easier reuse, always use the full cmdlet name and type out the complete parameter name—no positional parameters and no abbreviated parameter names. Doing so makes that file easier to read and understand in the future, and because you won't have to type the parameter names repeatedly (that's why you pasted the command into a file, after all), you won't be creating extra typing work for yourself.

FINDING POSITIONAL PARAMETERS IN THE FULL HELP

We said that you can locate positional parameters in two ways. The second requires that you open the help file by using the `-full` parameter of the `Help` command.

TRY IT NOW Run `Help Get-EventLog -full`. Remember to use the spacebar to view the help file one page at a time, and to press `Ctrl-C` if you want to stop viewing the file before reaching the end. For now, page through the entire

file, which lets you scroll back and review it all. Also, instead of `-full`, try using the `-ShowWindow` parameter, which should work on any client computer or server with a GUI. Be aware that the success of using `-ShowWindow` depends on the quality of the underlying help XML file. If the file is malformed, you might not see everything. Note that `-ShowWindow` doesn't work on non-Windows operating systems.

Page down until you see the help entry for the `-LogName` parameter. It should look something like the following:

```
-LogName <string>
    Specifies the event log. Enter the log name (the value of the Log property; not the LogDisplayName) of one event log. Wildcard characters are not permitted. This parameter is required.
    Required?           true
    Position?          1
    Default value
    Accept pipeline input?   false
    Accept wildcard characters? False
```

In the preceding example, you can see that this is a mandatory parameter; it's listed as required. Further, it's a positional parameter, and it occurs in the first position, right after the cmdlet name.

We always encourage students to focus on reading the full help when they're getting started with a cmdlet, rather than only the abbreviated syntax reminder. Reading the help reveals more details, including that description of the parameter's use. You can also see that this parameter doesn't accept wildcards, which means you can't provide a value like `App*`. You need to type out the full log name, such as `Application`.

3.5.4 Parameter values

The help files also give you clues about the kind of input that each parameter accepts. Some parameters, referred to as *switches*, don't require any input value at all. In the abbreviated syntax, they look like the following:

```
[-AsString]
```

And in the full syntax, they look like this:

```
-AsString [<SwitchParameter>]
    Returns the output as strings, instead of objects.
    Required?           false
    Position?          named
    Default value
    Accept pipeline input?   false
    Accept wildcard characters? False
```

The `[<SwitchParameter>]` part confirms that this is a switch, and that it doesn't expect an input value. Switches are never positional; you always have to type the

parameter name (or at least an abbreviated version of it). Switches are always optional, which gives you the choice to use them or not.

Other parameters expect some kind of input value, which will always follow the parameter name and be separated from the parameter name by a space (and not by a colon, equal sign, or any other character, although you might encounter exceptions from time to time). In the abbreviated syntax, the type of input expected is shown in angle brackets (our friend Jason calls them *chi-hua-huas* and has a whole little hand sign that he makes when he says it), like < >:

```
[-LogName] <string>
```

It's shown the same way in the full syntax:

```
-Message <string>
    Gets events that have the specified string in their messages.
    You can use this property to search for messages that contain certain words or phrases. Wildcards are permitted.
    Required?           false
    Position?          named
    Default value
    Accept pipeline input?   false
    Accept wildcard characters? True
```

Let's look at some common types of input:

- **String**—A series of letters and numbers. These can sometimes include spaces, but when they do, the entire string must be contained within quotation marks. For example, a string value such as C:\Windows doesn't need to be enclosed in quotes, but C:\Program Files does, because it has that space in the middle. For now, you can use single or double quotation marks interchangeably, but it's best to stick with single quotes.
- **Int, Int32, or Int64**—An integer number (a whole number with no decimal portion).
- **DateTime**—Generally, a string that can be interpreted as a date based on your computer's regional settings. In the United States, that's usually something like 10-10-2010, with the month, day, and year.

We'll discuss other, more specialized types as we come to them.

You'll also notice some values that have more square brackets:

```
[-ComputerName <string []>]
```

The side-by-side brackets (our friend Jason calls them *binkies*) after string don't indicate that something is optional. Instead, string[] indicates that the parameter can accept an *array*, a *collection*, or a *list* of strings. In these cases, it's always legal to provide a single value:

```
Get-EventLog Security -computer Server-R2
```

But it's also legal to specify multiple values. A simple way to do so is to provide a comma-separated list. PowerShell treats all comma-separated lists as arrays of values:

```
Get-EventLog Security -computer Server-R2,DC4,Files02
```

Once again, any individual value that contains a space must be enclosed in quotation marks. But the entire list doesn't get enclosed in quotation marks; it's important that only individual values be in quotes. The following is legal:

```
Get-EventLog Security -computer 'Server-R2','Files02'
```

Even though neither of those values needs to be in quotation marks, it's OK to use the quotes if you want to. But the following is wrong:

```
Get-EventLog Security -computer 'Server-R2,Files01'
```

In this case, the cmdlet will look for a single computer named Server-R2,Files01, which probably isn't what you want.

Another way to provide a list of values is to type them into a text file, with one value per line. Here's an example:

```
Server-R2  
Files02  
Files03  
DC04  
DC03
```

Next, you can use the `Get-Content` cmdlet to read the contents of that file, and send those contents into the `-computerName` parameter. You do this by forcing the shell to execute the `Get-Content` command first, so that the results get fed to the parameter.

Remember in high school math how parentheses, (), could be used to specify the order of operations in a mathematical expression? The same thing works in PowerShell: By enclosing a command in parentheses, you force that command to execute first:

```
Get-EventLog Application -computer (Get-Content names.txt)
```

The previous example shows a useful trick. We have text files with the names of different classes of computers—web servers, domain controllers, database servers, and so forth—and then we use this trick to run commands against entire sets of computers.

You can also feed a list of values to a parameter in a few other ways, including reading computer names from Active Directory. Those techniques are a bit more complex, though, so we'll get to them in later chapters, after you learn some of the cmdlets you need to make the trick work.

Another way you can specify multiple values for a parameter (provided it's a mandatory parameter) is to not specify the parameter at all. As with all mandatory parameters, PowerShell will prompt you for the parameter value. For parameters that accept multiple values, you can type the first value and press Enter. PowerShell will then prompt for a second value, which you can type and finish by hitting Enter. Keep doing

that until you’re finished, and press Enter on a blank prompt to let PowerShell know you’re finished. As always, you can press Ctrl-C to abort the command if you don’t want to be prompted for entries.

3.5.5 Finding command examples

We tend to learn by example, which is why we try to squeeze as many examples into this book as possible. PowerShell’s designers know that most administrators enjoy having examples, so they built a lot of them into the help files. If you’ve scrolled to the end of the help file for `Get-EventLog`, you probably noticed almost a dozen examples of how to use the cmdlet.

Let’s look at an easier way to get to those examples, if they’re all you want to see: Use the `-example` parameter of the `Help` command, rather than the `-full` parameter.
`Help Get-EventLog -example`

TRY IT NOW Go ahead and pull up the examples for a cmdlet by using this new parameter.

We love having these examples, even though some of them can be complicated. If an example looks too complicated for you, ignore it and examine the others for now. Or experiment a bit (always on a nonproduction computer) to see if you can figure out what the example does and why.

3.6 Accessing “about” topics

Earlier in this chapter, we mentioned that PowerShell’s help system includes background topics as well as help for specific cmdlets. These background topics are often called about topics, because their filenames all start with `about_`. You may also recall from earlier in this chapter that all cmdlets support a set of common parameters. How do you think you could learn more about those common parameters?

TRY IT NOW Before you read ahead, see if you can list the common parameters by using the help system.

You start by using wildcards. Because the word *common* has been used repeatedly here in the book, that’s probably a good keyword to start with:

```
Help *common*
```

It’s such a good keyword, in fact, that it matches only one help topic: `About_common_parameters`. That topic displays automatically because it’s the only match. Paging through the file a bit, you’ll find the following list of the eight common parameters:

```
-Verbose  
-Debug  
-WarningAction  
-WarningVariable  
-ErrorAction  
-ErrorVariable
```

```
-OutVariable  
-OutBuffer
```

The file says that PowerShell has two additional *risk mitigation* parameters, but those aren't supported by every single cmdlet.

The *about* topics in the help system are tremendously important, but because they're not related to a specific cmdlet, they can be easy to overlook. If you run `help about*` for a list of all of them, you might be surprised at how much extra documentation is hidden away inside the shell.

3.7 Accessing online help

Mere human beings wrote PowerShell's help files, which means they're not error-free. In addition to updating the help files (which you can do by running `Update-Help`), Microsoft publishes help on its website. The `-online` parameter of PowerShell's `help` command will attempt to open the web-based help—even on macOS or Linux!—for a given command:

```
Help Get-EventLog -online
```

Microsoft's TechNet website hosts the help, and it's often more up-to-date than what's installed with PowerShell itself. If you think you've spotted an error in an example or in the syntax, try viewing the online version of the help. Not every single cmdlet in the universe has online help; it's up to each product team (such as the Exchange team, the SQL Server team, the SharePoint team, and so forth) to provide that help. But when it's available, it's a nice companion to what's built in.

We like the online help because it lets us read the text in one window (the web browser, where the help is also nicely formatted) as we're typing in PowerShell. Don is fortunate enough to use dual monitors, which makes for a convenient setup. You can also use the `-ShowWindow` switch we mentioned earlier, instead of `-Online`, to pop up the local help in a separate window.

It's important for us to point out that the PowerShell team at Microsoft has open sourced all of their help files as of April 2016. Anyone can add examples, correct errors, and generally help improve the help files. The online, open source project is at <https://github.com/PowerShell/> and typically includes only the documentation owned by the PowerShell team itself; it doesn't necessarily include documentation from other teams who are producing PowerShell commands. You can bug those teams directly about open sourcing their docs!

3.8 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

We hope this chapter has conveyed the importance of mastering the help system in PowerShell. Now it's time to hone your skills by completing the following tasks. Keep in mind that sample answers follow. Look for *italicized* words in these tasks, and use

them as clues to complete the tasks. A few of these are Windows-only, and we point out which ones those are.

- 1 Run `Update-Help` and ensure that it completes without errors, so that you have a copy of the help on your local computer. You need an internet connection, and the shell needs to run under elevated privileges (which means *Administrator* must appear in the shell window's title bar).
- 2 Windows-only: can you find any cmdlets capable of converting other cmdlets' output into *HTML*?
- 3 Partially Windows-only: are there any cmdlets that can redirect output into a *file*, or to a *printer*?
- 4 How many cmdlets are available for working with *processes*? (Hint: remember that cmdlets all use a singular noun.)
- 5 What cmdlet might you use to *write* to an event *log*? (This one's possible on non-Windows operating systems, but you'll get a different answer.)
- 6 You've learned that aliases are nicknames for cmdlets; what cmdlets are available to create, modify, export, or import *aliases*?
- 7 Is there a way to keep a *transcript* of everything you type in the shell, and save that transcript to a text file?
- 8 Windows-only: it can take a long time to retrieve all of the entries from the Security *event* log. How can you get only the 100 most recent entries?
- 9 Windows-only: is there a way to retrieve a list of the *services* that are installed on a remote computer?
- 10 Is there a way to see what *processes* are running on a remote computer? (You can find the answer on non-Windows operating systems, but the command itself might not work for you.)
- 11 Examine the help file for the `Out-File` cmdlet. The files created by this cmdlet default to a width of how many characters? Is there a parameter that would enable you to change that width?
- 12 By default, `Out-File` overwrites any existing file that has the same filename as what you specify. Is there a parameter that would prevent the cmdlet from overwriting an existing file?
- 13 How could you see a list of all *aliases* defined in PowerShell?
- 14 Using both an alias and abbreviated parameter names, what is the shortest command line you could type to retrieve a list of running processes from a computer named *Server1*?
- 15 How many cmdlets are available that can deal with generic objects? (Hint: remember to use a singular noun like *object* rather than a plural one like *objects*.)
- 16 This chapter briefly mentioned *arrays*. What help topic could tell you more about them?

3.9 Lab answers

1 Update-Help

Or if you run it more than once in a single day:

Update-Help -force

2 help html

Or you could try with Get-Command:

get-command -noun html

3 get-command -noun file,printer

4 Get-command -noun process

or

Help *Process

5 get-command -verb write -noun eventlog

Or if you aren't sure about the noun, use a wildcard:

help *log

6 help *alias

or

get-command -noun alias

7 help transcript

8 help Get-Eventlog -parameter Newest

9 help Get-Service -parameter computername

10 help Get-Process -parameter computername

11 Help Out-File -full

or

Help Out-File -parameter Width

should show you 80 characters as the default for the PowerShell console. You would use this parameter to change it as well.

12 If you run Help Out-File -full and look at parameters, you should see -NoClobber.

13 Get-Alias

14 ps -c server1

15 get-command -noun object

16 help about_arrays

Or you could use wildcards:

help *array*

Running commands

When you start looking at PowerShell examples on the internet, it's easy to get the impression that PowerShell is some kind of .NET Framework-based scripting or programming language. Our fellow Microsoft Most Valuable Professional (MVP) award recipients, and hundreds of other PowerShell users, are pretty serious geeks who like to dig deep into the shell to see what we can make it do. But almost all of us began right where this chapter starts: running commands. That's what you'll be doing in this chapter: not scripting, not programming, but running commands and command-line utilities.

4.1 Not scripting, but running commands

PowerShell, as its name indicates, is a *shell*. It's similar to the Cmd.exe command-line shell that you've probably used previously, and it's even similar to the good old MS-DOS shell that shipped with the first PCs back in the 1980s. It has a strong resemblance to the UNIX shells, such as Bash, from the late 1980s, or even the original UNIX Bourne shell, introduced in the late 1970s. PowerShell is much more modern, but in the end, PowerShell isn't a scripting language in the way VBScript or Kixtart were.

With those languages, as with most programming languages, you sit down in front of a text editor (even if it's Windows Notepad) and type a series of keywords to form a script. You save that file, and perhaps double-click it to test it. PowerShell can work like that, but that's not necessarily the main usage pattern for PowerShell, particularly when you're getting started. With PowerShell, you type a command,

add a few parameters to customize the command’s behavior, hit Enter, and immediately see your results.

Eventually, you’ll get tired of typing the same command (and its parameters) over and over again, so you’ll copy and paste it all into a text file. Give that file a .PS1 file-name extension, and you suddenly have a *PowerShell script*. Now, instead of typing the command over and over, you run that script, and it executes whatever commands are inside. This is the same pattern you may have used with batch files in the Cmd.exe shell, but it’s typically far less complex than scripting or programming. In fact, it’s a similar pattern to that used by UNIX administrators for years. Common UNIX/Linux shells, such as Bash, have a similar approach: Run commands until you get them right, and then paste them into a text file and call it a *script*.

Don’t get us wrong: You can get as complex as you need to with PowerShell. It does support the same kind of usage patterns as VBScript and other scripting or programming languages. PowerShell gives you access to the full underlying power of the .NET Framework (although on non-Windows operating systems, it’s a subset of the full Framework), and we’ve seen PowerShell “scripts” that were practically indistinguishable from a C# program written in Visual Studio. PowerShell supports these different usage patterns because it’s intended to be useful to a wide range of audiences. The point is that just because it *supports* that level of complexity doesn’t mean you *have* to use it at that level, and it doesn’t mean you can’t be extremely effective with less complexity.

Here’s an analogy: You probably drive a car. If you’re like us, changing the oil is the most complex mechanical task you’ll ever do with your car. We’re not car geeks and can’t rebuild an engine. We also can’t do those cool, high-speed J-turns that you see in the movies. You’ll never see us driving a car on a closed course in a car commercial, although Jeff dreams about it (he watches too much *Top Gear*). But the fact that we’re not professional stunt drivers doesn’t stop us from being extremely effective drivers at a less complex level. Someday we might decide to take up stunt driving for a hobby (our insurance companies will be thrilled), and at that point we’ll need to learn a bit more about how our cars work, master some new skills, and so on. The option is always there for us to grow into. But for now, we’re happy with what we can accomplish as normal drivers.

For now, we’ll stick with being normal “PowerShell drivers,” operating the shell at a lower level of complexity. Believe it or not, users at this level are the primary target audience for PowerShell, and you’ll find that you can do a lot of incredible stuff without going beyond this level. All you need to do is master the ability to run commands within the shell, and you’re on your way.

4.2 **The anatomy of a command**

Figure 4.1 shows the basic anatomy of a complex PowerShell command. We call this the *full-form* syntax of a command. We’re showing a somewhat complex command so you can see all of the things that might show up.

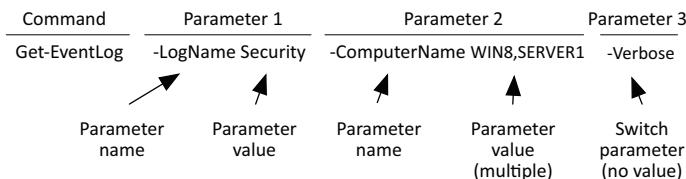

Figure 4.1 The anatomy of a PowerShell command

To make sure you're completely familiar with PowerShell's rules, let's cover each of the elements in the previous figure in more detail:

- The cmdlet name is `Get-EventLog`. PowerShell cmdlets always have this verb-noun naming format. We explain more about cmdlets in the next section.
- The first parameter name is `-LogName`, and it's being given the value `Security`. Because the value doesn't contain any spaces or punctuation, it doesn't need to be in quotation marks.
- The second parameter name is `-ComputerName`, and it's being given two values: `WIN8` and `SERVER1`. These are in a comma-separated list, and because neither value contains spaces or punctuation, neither value needs to be inside quotation marks.
- The final parameter, `-Verbose`, is a switch parameter. That means it doesn't get a value; specifying the parameter is sufficient.
- Note that there's a mandatory space between the command name and the first parameter.
- Parameter names always start with a dash (-).
- There's a mandatory space after the parameter name, and between the parameter's value and the next parameter name.
- There's no space between the dash (-) that precedes a parameter name and the parameter name itself.
- Nothing here is case-sensitive.

Get used to these rules. Start being sensitive about accurate, neat typing. Paying attention to spaces and dashes and other rules will minimize the silly errors that PowerShell throws at you.

4.3 The cmdlet naming convention

First, let's discuss some terminology. As far as we know, we're the only ones who use this terminology in everyday conversation, but we do it consistently, so we may as well explain:

- A *cmdlet* is a native PowerShell command-line utility. These exist only inside PowerShell and are written in a .NET Framework language such as C#. The word *cmdlet* is unique to PowerShell, so if you add it to your search keywords on Google or Bing, the results you get back will be mainly PowerShell-related. The word is pronounced *com-mand-let*.

- A *function* can be similar to a cmdlet, but rather than being written in a .NET language, functions are written in PowerShell’s own scripting language.
- A *workflow* is a special kind of function that ties into PowerShell’s workflow execution system.
- An *application* is any kind of external executable, including command-line utilities such as Ping and Ipconfig.
- *Command* is the generic term that we use to refer to any or all of the preceding terms.

Microsoft has established a naming convention for cmdlets. That same naming convention *should* be used for functions and workflows, too, although Microsoft can’t force anyone but its own employees to follow that rule.

The rule is this: Names start with a standard verb, such as Get or Set or New or Pause. You can run Get-Verb to see a list of allowable verbs (you’ll see about 100, although only about a dozen are common). After the verb is a dash, followed by a singular noun, such as Service or Process or EventLog. Developers get to make up their own nouns, so there’s no *Get-Noun* cmdlet to display them all.

What’s the big deal about this rule? Well, suppose we told you that there were cmdlets named New-Service, Get-Service, Get-Process, Set-Service, and so forth. Could you guess what command would create a new Exchange mailbox? Could you guess what command would modify an Active Directory user? If you guessed Get-Mailbox, you got the first one right. If you guessed Set-User, you were close: it’s Set-ADUser, and you’ll find the command on domain controllers in the Active-Directory module. The point is that by having this consistent naming convention with a limited set of verbs, it becomes possible for you to guess at command names, and you could then use Help or Get-Command, along with wildcards, to validate your guess. It becomes easier for you to figure out the names of the commands you need, without having to run to Google or Bing every time.

OK, OK Not all of the so-called verbs are really verbs. Although Microsoft officially uses the term *verb-noun naming convention*, you’ll see “verbs” like New, Where, and so forth. You’ll get used to it.

4.4 *Aliases: nicknames for commands*

Although PowerShell command names can be nice and consistent, they can also be long. A command name such as Set-WinDefaultInputMethodOverride is a lot to type, even with Tab completion. Although the command name is clear—looking at it, you can probably guess what it does—it’s an *awful* lot to type.

That’s where PowerShell aliases come in. An *alias* is nothing more than a nickname for a command. Tired of typing Get-Service? Try this:

```
PS C:\> get-alias -Definition "Get-Service"
Capability      Name
-----          -----
Cmdlet          gsv -> Get-Service
```

Now you know that gsv is an alias for Get-Service.

When using an alias, the command works in exactly the same way. Parameters are the same, everything is the same—the command name is just shorter. If you’re used to UNIX or Linux, where an alias can also include some parameters, just know that PowerShell doesn’t work that way.

If you’re staring at an alias (folks on the internet tend to use them as if we’ve all memorized the hundreds of built-in aliases) and can’t figure out what it is, ask help:

```
PS C:\> help gsv

NAME
    Get-Service
SYNOPSIS
    Gets the services on a local or remote computer.
SYNTAX
    Get-Service [[-Name] <String[]>] [-ComputerName <String[]>]
    [-DependentServices [<SwitchParameter>]] [-Exclude <String[]>]
    [-Include <String[]>] [-RequiredServices [<SwitchParameter>]]
    [<CommonParameters>]
    Get-Service [-ComputerName <String[]>] [-DependentServices
    [<SwitchParameter>]] [-Exclude <String[]>] [-Include <String[]>]
    [-RequiredServices [<SwitchParameter>]] -DisplayName <String[]>
    [<CommonParameters>]
    Get-Service [-ComputerName <String[]>] [-DependentServices
    [<SwitchParameter>]] [-Exclude <String[]>] [-Include <String[]>]
    [-InputObject <ServiceController[]>] [-RequiredServices
    [<SwitchParameter>]] [<CommonParameters>]
```

When asked for help about an alias, the help system will always display the help for the full command, which includes the command’s complete name.

Above and beyond

You can create your own aliases by using New-Alias, export a list of aliases by using Export-Alias, or even import a list of previously created aliases by using Import-Alias. When you create an alias, it lasts only as long as your current shell session. Once you close the window, it’s gone. That’s why you might want to export them, so that you can more easily reimport them.

We tend to avoid creating and using custom aliases, though, because they’re not available to anyone but us. If someone can’t look up what xtd does, we’re creating confusion and incompatibility.

And xtd doesn’t do anything. It’s a fake alias we made up.

We must point out, because PowerShell is now available on non-Windows operating systems, that its concept of *alias* is a little different from an alias on, say, Linux. On Linux, an alias can be a kind of shortcut for running a command *that includes a bunch of parameters*. PowerShell doesn’t behave that way. An alias is *only* a nickname for the command name, and the alias can’t include any predetermined parameters.

4.5 Taking shortcuts

Here's where PowerShell gets tricky. We'd love to tell you that everything we've shown you so far is the only way to do things, but we'd be lying. And, unfortunately, you're going to be out on the internet stealing (er, repurposing) other people's examples, and you'll need to know what you're looking at.

In addition to aliases, which are shorter versions of command names, you can also take *shortcuts* with parameters. You have three ways to do this, each potentially more confusing than the last.

4.5.1 Truncating parameter names

PowerShell doesn't force you to type out entire parameter names. Instead of typing `-computerName`, for example, you could go with `-comp`. The rule is that you have to type enough of the name for PowerShell to be able to distinguish it. If there's a `-computerName` parameter, a `-common` parameter, and a `-composite` parameter, you'd have to type at least `-compu`, `-commo`, and `-compo`, because that's the minimum number of letters necessary to uniquely identify each.

If you must take shortcuts, this isn't a bad one to take, if you can remember to hit Tab after typing that minimum-length parameter so that PowerShell can finish typing the rest of it for you.

4.5.2 Using parameter name aliases

Parameters can also have their own aliases, although they can be terribly difficult to find, as they aren't displayed in the help files or anywhere else convenient. For example, the `Get-EventLog` command has a `-computerName` parameter. To discover its aliases, you run this command:

```
PS C:\> (get-command get-eventlog | select -ExpandProperty parameters)
    .computername.alises
```

We've boldfaced the command and parameter names; replace these with whatever command and parameter you're curious about. In this case, the output reveals that `-Cn` is an alias for `-ComputerName`, so you could run this:

```
PS C:\> Get-EventLog -LogName Security -Cn SERVER2 -Newest 10
```

Tab completion will show you the `-Cn` alias; if you typed `Get-EventLog -C` and started pressing Tab, it'd show up. But the help for the command doesn't display `-Cn` at all, and Tab completion doesn't indicate that `-Cn` and `-ComputerName` are the same thing.

4.5.3 Using positional parameters

When you're looking at a command's syntax in its help file, you can spot positional parameters easily:

SYNTAX

```
Get-ChildItem [[-Path] <String[]>] [[-Filter] <String>] [-Exclude
```

```
<String[]>] [-Force [<SwitchParameter>]] [-Include <String[]>] [-Name
[<SwitchParameter>]] [-Recurse [<SwitchParameter>]] [-UseTransaction
[<SwitchParameter>]] [<CommonParameters>]
```

Here, both `-Path` and `-Filter` are positional, and you know that because the parameter name is contained within square brackets. A clearer explanation is available in the full help (`help Get-ChildItem -full`, in this case), which looks like this:

```
-Path <String[]>
    Specifies a path to one or more locations. Wildcards are
    permitted. The default location is the current directory (.).
    Required?           false
    Position?          1
    Default value      Current directory
    Accept pipeline input? true (ByValue, ByPropertyName)
    Accept wildcard characters? True
```

That's a clear indication that the `-Path` parameter is in position 1. For positional parameters, you don't have to type the parameter name; you can provide its value in the correct position. For example

```
PS C:\> Get-ChildItem c:\users

Directory: C:\users
Mode                LastWriteTime      Length Name
----                -----          ----- ----
d----        3/27/2016 11:20 AM            donjones
d-r--        2/18/2016 2:06 AM            Public
```

That's the same as this:

```
PS C:\> Get-ChildItem -path c:\users

Directory: C:\users
Mode                LastWriteTime      Length Name
----                -----          ----- ----
d----        3/27/2016 11:20 AM            donjones
d-r--        2/18/2016 2:06 AM            Public
```

The problem with positional parameters is that you're taking on the responsibility of remembering what goes where. You must type all positional parameters first, in the correct order, before you can add any named (nonpositional) parameters. If you mix up the parameter order, the command fails. For simple commands such as `Dir`, which you've probably used for years, typing `-Path` feels weird, and almost nobody does it. But for more-complex commands, which might have three or four positional parameters in a row, it can be tough to remember what goes where.

For example, this is a bit difficult to read and interpret:

```
PS C:\> move file.txt users\donjones\
```

This version, which uses parameter names, is easier to follow:

```
PS C:\> move -Path c:\file.txt -Destination \users\donjones\
```

This version, which puts the parameters in a different order, is allowed when you use the parameter names:

```
PS C:\> move -Destination \users\donjones\ -Path c:\file.txt
```

We tend to recommend against using positional (unnamed) parameters unless you're banging out something quick and dirty at the command line. In anything that will persist, such as a batch file or a blog post, include all of the parameter names. We do that as much as possible in this book, except in a few instances where we have to shorten the command line to make it fit within the printed pages.

4.6 **Cheating a bit: Show-Command**

Despite our long experience using PowerShell, the complexity of the commands' syntax can sometimes drive us nuts. One cool new feature of PowerShell v3 (and later, although not on non-Windows operating systems) is the `Show-Command` cmdlet. If you're having trouble getting a command's syntax right, with all the spaces, dashes, commas, quotes, and whatnot, `Show-Command` is your friend. It lets you specify the command name you're struggling with and then graphically prompts you for the command's parameters. As shown in figure 4.2, each parameter set (which you learned about in the previous chapter) is on a separate tab, so there's no chance of mixing and matching parameters across sets. Pick a tab and stick with it. Note that this won't work on a server OS that doesn't have a GUI installed.

When you're finished, you can either click Run to run the command or—and we like this option better—click Copy to put the completed command on the clipboard. Back in the shell, paste the command (right-click in the console, or press Ctrl-V in the ISE) to look at it. This is a great way to teach yourself the proper syntax, as shown in figure 4.3, and you'll get the proper syntax every time.

When you produce a command this way, you'll always get the full-form command: full command name, full parameter names, all parameter names typed (nothing entered positionally), and so on. It's a great way to see the perfect, preferred, best-practice way of using PowerShell.

Unfortunately, `Show-Command` works only with single commands. When you start stringing together multiple commands, it can help you with only one at a time.

4.7 **Support for external commands**

So far, all of the commands you've run in the shell (at least, the ones we've suggested that you run) have been built-in cmdlets. Almost 400 of those cmdlets come built into the Windows client operating system, and thousands into the server operating system. You can add more—products such as Exchange Server, SharePoint Server, and SQL Server all come with add-ins that include hundreds of additional cmdlets.

But you're not limited to the cmdlets that come with PowerShell. You can also use the same external command-line utilities that you've probably been using for years, including Ping, Nslookup, Ipconfig, Net, and so forth. Because these aren't native

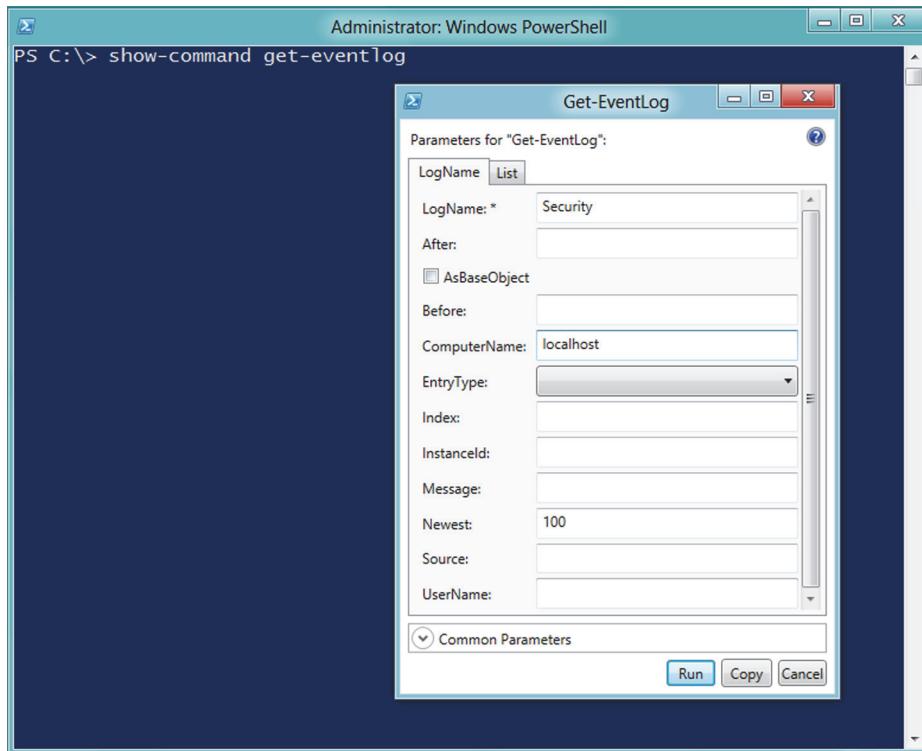

Figure 4.2 Show-Command uses a graphical prompt to complete command parameters.

PowerShell cmdlets, you use them the same way that you always have. PowerShell will launch Cmd.exe behind the scenes, because it knows how to run those external commands, and any results will be displayed within the PowerShell window. Go ahead and try a few old favorites right now. We're often asked how you can use PowerShell to map a regular network drive—one that can be seen from within Explorer. We always use `Net Use`, and it works fine within PowerShell.

It's the same story on non-Windows operating systems: You can use `grep`, `bash`, `sed`, `awk`, `ping`, and whatever other existing command-line tools you may have. They'll

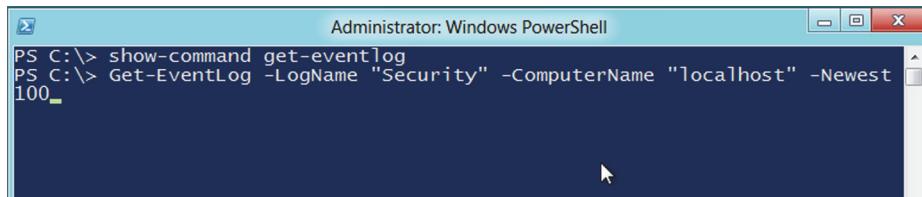

Figure 4.3 Show-Command produces the proper command-line syntax based on your entries in its dialog box.

run normally, and PowerShell will display their results the same way that your old shell (for example, Bash) would have.

TRY IT NOW Try running some external command-line utilities that you've used previously. Do they work the same? Do any of them fail?

The `Net Use` example illustrates an important lesson: With PowerShell, Microsoft (perhaps for the first time ever) isn't saying, "You have to start over and learn everything all over again." Instead, Microsoft is saying, "If you already know how to do something, keep doing it that way. We'll try to provide you with better and more complete tools going forward, but what you already know will still work." One reason there's no *Map-Drive* command within PowerShell is that `Net Use` already does a good job, so why not keep using it?

NOTE We've been using that `Net Use` example for years—ever since PowerShell v1 first came out. It's still a good story, but PowerShell v3 proved that Microsoft is starting to find the time to create PowerShell-ish ways to do those old tasks. Starting with v3, you'll find that the `New-PSDrive` command now has a `-Persist` parameter, which—when used with the `FileSystem` provider—creates drives that are visible in Explorer.

In some instances, Microsoft has provided better tools than some of the existing, older ones. For example, the native `Test-Connection` cmdlet provides more options and more-flexible output than the old, external ping command. But if you know how to use Ping, and it's solving whatever need you have, go right on using it. It'll work fine from within PowerShell.

All that said, we do have to deliver a harsh truth: Not every external command will work flawlessly from within PowerShell, at least not without a little tweaking on your part. That's because PowerShell's parser—the bit of the shell that reads what you've typed and tries to figure out what you want the shell to do—doesn't always guess correctly. Sometimes you'll type an external command, and PowerShell will mess up, start spitting out errors, and generally not work.

For example, things can get tricky when an external command has a lot of parameters—that's where you'll see PowerShell break the most. We won't dive into the details of why it works, but here's a way to run a command that ensures that its parameters will work properly:

```
$exe = "C:\Vmware\vcbMounter.exe"
$host = "server"
$user = "joe"
$password = "password"
$machine = "somepc"
$location = "somedirection"
$backupType = "incremental"
& $exe -h $host -u $user -p $password -s "name:$machine" -r $location -t
$backupType
```

This supposes that you have an external command named `vcbMounter.exe`. (This real-life command-line utility is supplied with some of VMWare's virtualization products. If you've never used it or don't have it, that's fine; most old-school command-line utilities work the same way, so this is still a good teaching example.) It accepts several parameters:

- -h for the host name
- -u for the user name
- -p for the password
- -s for the server name
- -r for a location
- -t for a backup type

What we've done is put all the various elements—the executable path and name, as well as all of the parameter values—into placeholders, which start with the \$ character. That forces PowerShell to treat those values as single units, rather than trying to parse them to see whether any contain commands or special characters. Then we used the invocation operator (&), passing it the executable name, all of the parameters, and the parameters' values. That pattern will work for almost any command-line utility that's being grumpy about running within PowerShell.

Sound complicated? Well, here's some good news: In PowerShell v3 and later, you don't have to mess around so much. Just add two dashes and a percent symbol in front of any external command. When you do so, PowerShell won't even try to parse the command; it'll just pass it out to Cmd.exe. You can essentially run anything, using the exact syntax you would in Cmd.exe, and not worry about explaining it to PowerShell! To be absolutely clear, this means you won't be able to pass variables as parameter values.

Here's a quick example of what will fail:

```
PS C:\> $n = "bits"
PS C:\> C:\windows\system32\sc.exe --% qc $n
[SC] OpenService FAILED 1060:
The specified service does not exist as an installed service.
```

We tried to run the command-line utility `sc.exe` to query a service. But if we explicitly state what we want, PowerShell will pass all the parameters to the underlying command without trying to do anything with them.

```
PS C:\> C:\windows\system32\sc.exe --% qc bits
[SC] QueryServiceConfig SUCCESS

SERVICE_NAME: bits
    TYPE               : 20  WIN32_SHARE_PROCESS
    START_TYPE         : 2   AUTO_START  (DELAYED)
    ERROR_CONTROL     : 1   NORMAL
    BINARY_PATH_NAME  : C:\windows\System32\svchost.exe -k netsvcs
    LOAD_ORDER_GROUP  :
    TAG               : 0
    DISPLAY_NAME      : Background Intelligent Transfer Service
```

```

DEPENDENCIES      : RpcSs
                     : EventSystem
SERVICE_START_NAME : LocalSystem
PS C:\>

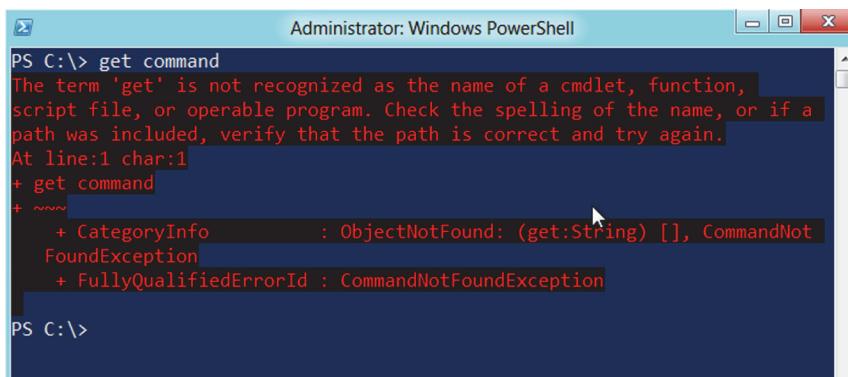

```

Hopefully, this isn't something you'll need to do often.

4.8 Dealing with errors

It's inevitable that you'll see some ugly red text as you start working with PowerShell—and probably from time to time even after you're an expert-level shell user. Happens to us all. But don't let the red text stress you out. (Personally, it takes us back to high school English class and poorly written essays, so *stress* is putting it mildly.)

The alarming red text aside, PowerShell's error messages are intended to be helpful. For example, as shown in figure 4.4, they try to show you exactly where PowerShell ran into trouble.

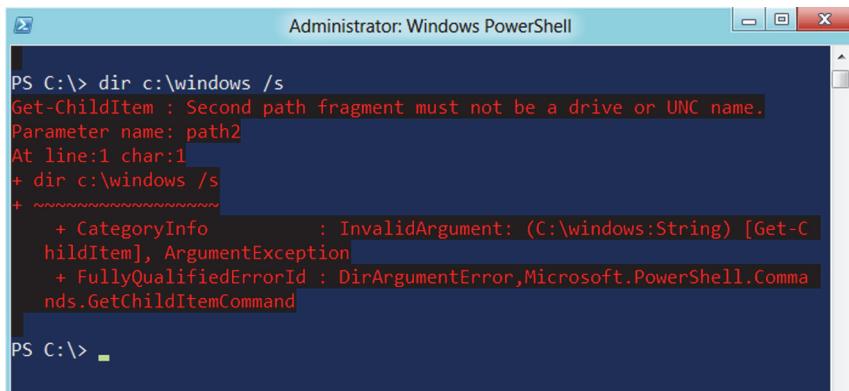

A screenshot of a Windows PowerShell window titled "Administrator: Windows PowerShell". The window shows a command being typed: "PS C:\> get command". An error message follows: "The term 'get' is not recognized as the name of a cmdlet, function, script file, or operable program. Check the spelling of the name, or if a path was included, verify that the path is correct and try again." Below the error message, the command line continues with "+ get command" and then shows the stack trace of the error: "At line:1 char:1 + get command + ~~~ + CategoryInfo : ObjectNotFound: (get:String) [], CommandNotFoundException + FullyQualifiedErrorId : CommandNotFoundException". The PowerShell prompt "PS C:\>" is visible at the bottom.

Figure 4.4 Interpreting a PowerShell error message

Error messages almost always include the line and char (character) number where PowerShell got confused. In figure 4.4, it's line 1, char 1—right at the beginning. It's saying, “You typed `get`, and I have no idea what that means.” That's because we typed the command name wrong: It's supposed to be `Get-Command`, not `Get Command`. Oops. What about figure 4.5?

The error message in figure 4.5, “Second path fragment must not be a drive or UNC name,” is confusing. What second path? We didn't type a second path. We typed one path, `c:\windows`, and a command-line parameter, `/s`. Right?

Well, no. One of the easiest ways to solve this kind of problem is to read the help and to type the command out completely. If we'd typed `Get-ChildItem -path C:\Windows`, we'd have realized that `/s` isn't the correct syntax. We meant `-recurse`. Sometimes the error message might not seem helpful—and if it seems like you and PowerShell are speaking different languages, you are. PowerShell obviously isn't going to change its language, so you're probably the one in the wrong, and consulting the help and

```
Administrator: Windows PowerShell
PS C:\> dir c:\windows /s
Get-ChildItem : Second path fragment must not be a drive or UNC name.
Parameter name: path2
At line:1 char:1
+ dir c:\windows /s
+ ~~~~~~
    + CategoryInfo          : InvalidArgument: (C:\windows:String) [Get-ChildItem], ArgumentException
    + FullyQualifiedErrorId : DirArgumentError,Microsoft.PowerShell.Commands.GetChildItemCommand
PS C:\>
```

Figure 4.5 What's a “second path fragment?”

spelling out the entire command, parameters and all, is often the quickest way to solve the problem. And don't forget to use `Show-Command` to figure out the right syntax.

4.9 Common points of confusion

Whenever it seems appropriate, we wrap up each chapter with a brief section that covers some of the common mistakes we see when we teach classes. The idea is to help you see what most often confuses other administrators like yourself, and to avoid those problems—or at least to be able to find a solution for them—as you start working with the shell.

4.9.1 Typing cmdlet names

First up is the typing of cmdlet names. It's always verb-noun, like `Get-Content`. All of these are options we'll see newcomers try, but they won't work:

- `Get Content`
- `GetContent`
- `Get=Content`
- `Get_Content`

Part of the problem comes from typos (= instead of -, for example), and part from verbal laziness. We all pronounce the command as *Get Content*, verbally omitting the dash. But you have to type the dash.

4.9.2 Typing parameters

Parameters are also consistently written. A parameter that takes no value, such as `-recurse`, gets a dash before its name. You need to have spaces separating the cmdlet name from its parameters, and the parameters from each other. The following are correct:

- `Dir -rec` (the shortened parameter name is fine)
- `New-PSDrive -name DEMO -psprovider FileSystem -root \\Server\Share`

But these examples are all incorrect:

- Dir-rec (no space between alias and parameter)
- New-PSDrive -nameDEMO (no space between parameter name and value)
- New-PSDrive -name DEMO-psprovider FileSystem (no space between the first parameter's value and the second parameter's name)

PowerShell isn't normally picky about upper- and lowercase, meaning that `dir` and `DIR` are the same, as are `-RECURSE` and `-recurse` and `-Recurse`. But the shell sure is picky about those spaces and dashes.

4.10 Lab

NOTE For this lab, you need a Windows 8 or Windows Server 2012, or later, computer running PowerShell v3 or later.

Using what you learned in this chapter, and in the previous chapter on using the help system, complete the following tasks in Windows PowerShell:

- 1 Display a list of running processes.
- 2 Display the 100 most recent entries from the Application event log. (Don't use `Get-WinEvent` for this. We've shown you another command that will do this task.) This is for Windows operating systems only.
- 3 Display a list of all commands that are of the cmdlet type. (This is tricky—we've shown you `Get-Command`, but you're going to have to read the help to find out how to narrow down the list as we've asked.)
- 4 Display a list of all aliases.
- 5 Make a new alias, so you can run `np` to launch Notepad from a PowerShell prompt. This is for Windows only unless you've installed wine on Linux.
- 6 Display a list of services that begin with the letter *M*. Again, read the help for the necessary command—and don't forget that the asterisk (*) is a near-universal wildcard in PowerShell. Note that this will work only on Windows operating systems.
- 7 Display a list of all Windows Firewall rules. You'll need to use `Help` or `Get-Command` to discover the necessary cmdlet. Again, this will work only on Windows operating systems.
- 8 Display a list only of inbound Windows Firewall rules. You can use the same cmdlet as in the previous task, but you'll need to read its help to discover the necessary parameter and its allowable values. Once more, Windows operating systems only for this one.

We hope these tasks seem straightforward to you. If so—excellent. You're taking advantage of your existing command-line skills to make PowerShell perform a few practical tasks for you. If you're new to the command-line world, these tasks are a good introduction to what you'll be doing in the rest of this book.

5

Working with providers

One of the more potentially confusing aspects of PowerShell is its use of *providers*. We warn you that some of this chapter might seem a bit remedial for you. We expect that you're familiar with the Windows filesystem, for example, and you probably know all the commands you need to manage the filesystem from a command prompt. But bear with us: We're going to point things out in a specific way so that we can use your existing familiarity with the filesystem to help make the concept of providers easier to understand. Also, keep in mind that PowerShell isn't Cmd.exe. You may see some things in this chapter that look familiar, but we assure you that they're doing something quite different from what you're used to.

5.1 What are providers?

A PowerShell provider, or *PSPProvider*, is an adapter. It's designed to take some kind of data storage and make it look like a disk drive. You can see a list of installed PowerShell providers right within the shell:

```
PS C:\> Get-PSPProvider
```

Name	Capabilities	Drives
---	-----	-----
Alias	ShouldProcess	{Alias}
Environment	ShouldProcess	{Env}
FileSystem	Filter, ShouldProcess, Credentials	{C, A, D}
Function	ShouldProcess	{Function}
Registry	ShouldProcess, Transactions	{HKLM, HKCU}
Variable	ShouldProcess	{Variable}

Providers can also be added into the shell, typically along with a module or snap-in, which are the two ways that PowerShell can be extended. (We cover those extensions in chapter 7.) Sometimes, enabling certain PowerShell features may create a new PSProvider. For example, when you enable Remoting (which we discuss in chapter 13), you'll get a new WSMAN PSProvider, as you can see here:

```
PS C:\> Get-PSPProvider

Name          Capabilities      Drives
----          -----
Alias         ShouldProcess    {Alias}
Environment   ShouldProcess    {Env}
FileSystem    Filter, ShouldProcess, Credentials {C, A, D}
Function      ShouldProcess    {Function}
Registry      ShouldProcess, Transactions {HKLM, HKCU}
Variable     ShouldProcess    {Variable}
WSMan        Credentials      {WSMan}
```

Notice that each provider has different capabilities. This is important, because it affects the ways in which you can use each provider. These are some of the common capabilities you'll see:

- **ShouldProcess**—The provider supports the use of the `-WhatIf` and `-Confirm` parameters, enabling you to “test” certain actions before committing to them.
- **Filter**—The provider supports the `-Filter` parameter on the cmdlets that manipulate providers’ content.
- **Credentials**—The provider permits you to specify alternate credentials when connecting to data stores. There’s a `-Credential` parameter for this.
- **Transactions**—The provider supports the use of transactions, which allows you to use the provider to make several changes, and then either roll back or commit those changes as a single unit.

You use a provider to create a PSDrive. A *PSDrive* uses a single provider to connect to data storage. You’re creating a drive mapping, much as you might have in Windows Explorer, but a PSDrive, thanks to the providers, is able to connect to much more than disks. Run the following command to see a list of currently connected drives:

```
PS C:\> Get-PSDrive

Name          Used (GB)  Free (GB) Provider      Root
----          -----      -----      -----
A                         FileSystem    A:\
Alias                    Alias
C             9.88       54.12  FileSystem    C:\
D             3.34       96.64  FileSystem    D:\
Env
Function
HKCU
HKLM
Variable
```

In the preceding list, you can see that we have three drives using the `FileSystem` provider, two using the `Registry` provider, and so forth. The `PSProvider` adapts the data store, the `PSDrive` makes it accessible, and you use a set of cmdlets to see and manipulate the data exposed by each `PSDrive`. For the most part, the cmdlets you use with a `PSDrive` have the word `Item` somewhere in their noun:

```
PS C:\> get-command -noun *item*
```

Capability	Name
Cmdlet	Clear-Item
Cmdlet	Clear-ItemProperty
Cmdlet	Copy-Item
Cmdlet	Copy-ItemProperty
Cmdlet	Get-ChildItem
Cmdlet	Get-Item
Cmdlet	Get-ItemProperty
Cmdlet	Invoke-Item
Cmdlet	Move-Item
Cmdlet	Move-ItemProperty
Cmdlet	New-Item
Cmdlet	New-ItemProperty
Cmdlet	Remove-Item
Cmdlet	Remove-ItemProperty
Cmdlet	Rename-Item
Cmdlet	Rename-ItemProperty
Cmdlet	Set-Item
Cmdlet	Set-ItemProperty

We'll use these cmdlets, and their aliases, to begin working with the providers on our system. Because it's probably the one you're most familiar with, we'll start with the `filesystem`—the `FileSystem` `PSProvider`.

5.2 Understanding how the filesystem is organized

The Windows filesystem (and the filesystems on macOS and Linux) is organized around three main types of objects: drives, folders, and files. *Drives*, the top-level objects, contain both folders and files. *Folders* are also a kind of container, capable of containing both files and other folders. *Files* aren't a type of container; they're more of an endpoint object.

You're probably most familiar with viewing the filesystem through Windows Explorer, as shown in figure 5.1, where the hierarchy of drives, folders, and files is visually obvious.

PowerShell's terminology differs somewhat from that of the filesystem. Because a `PSDrive` might not point to a filesystem—for example, a `PSDrive` can be mapped to the Windows Registry, which is obviously not a filesystem—PowerShell doesn't use the terms *file* and *folder*. Instead, it refers to these objects by the more generic term *item*. Both a file and a folder are considered items, although they're obviously different types of items. That's why the cmdlet names we showed you previously all use `item` in their noun.

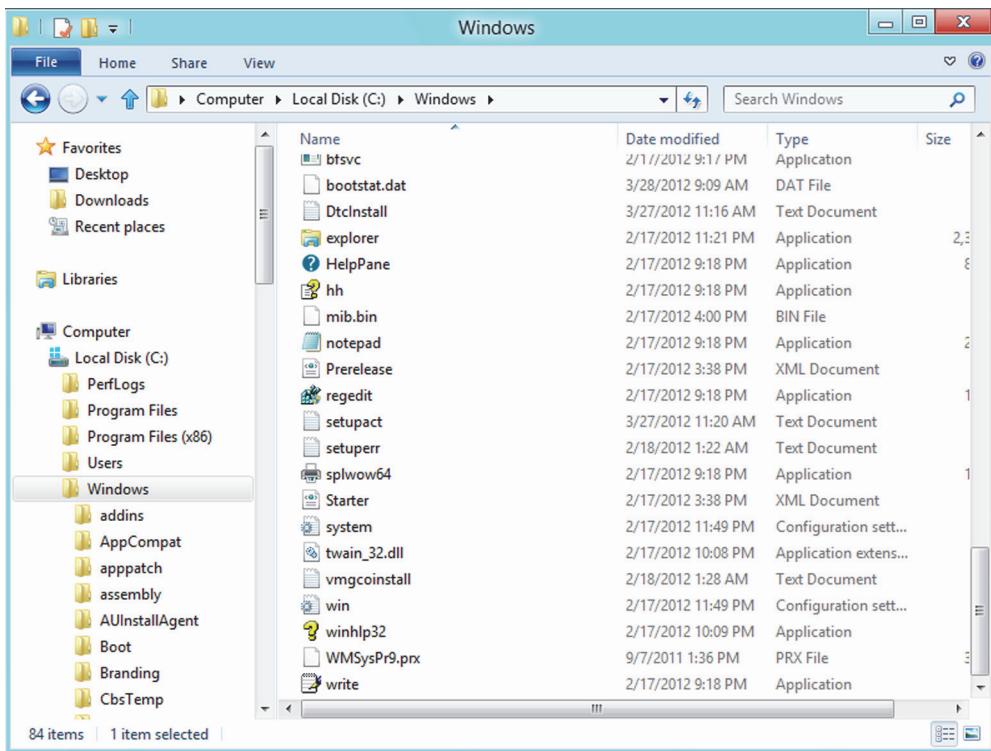

Figure 5.1 Viewing files, folders, and drives in Windows Explorer

Items can, and often do, have properties. For example, a file item might have properties including its last write time, whether or not it's read-only, and so on. Some items, such as folders, can have *child items*, which are the items contained within that item. Knowing those facts should help you make sense of the verbs and nouns in the command list we showed you earlier:

- Verbs such as Clear, Copy, Get, Move, New, Remove, Rename, and Set can all apply to items (for example, files and folders) as well as to item properties (such as the date the item was last written, or whether it's read-only).
- The `Item` noun refers to individual objects, such as files and folders.
- The `ItemProperty` noun refers to attributes of an item, such as read-only, creation time, length, and so on.
- The `ChildItem` noun refers to the items (such as files and subfolders) contained within an item (for example, a folder).

Keep in mind that these cmdlets are intentionally generic, because they're meant to work with a variety of data stores. Some of the cmdlets' capabilities don't make sense in certain situations. As an example, because the `FileSystem` provider doesn't support

the Transactions capability, none of the cmdlets' `-UseTransaction` parameters will work with items in the filesystem drives. Because the Registry doesn't support the Filter capability, the cmdlets' `-Filter` parameter won't work in the Registry drives.

Some PSProviders don't support item properties. For example, the Environment PSProvider is what's used to make the ENV: drive available in PowerShell. This drive provides access to the Windows environment variables, but as the following example shows, they don't have item properties:

```
PS C:\> Get-ItemProperty -Path Env:\PSModulePath
Get-ItemProperty : Cannot use interface. The IPropertyCmdletProvider
interface is not supported by this provider.
At line:1 char:1
+ Get-ItemProperty -Path Env:\PSModulePath
+ ~~~~~
+ CategoryInfo          : NotImplemented: () [Get-ItemProperty], PSN
+ CategoryInfo          : NotSupportedException
+ FullyQualifiedErrorId : NotSupported,Microsoft.PowerShell.Commands.
GetItemPropertyCommand
```

The fact that not every PSProvider is the same is perhaps what makes providers so confusing for PowerShell newcomers. You have to think about what each provider is giving you access to, and understand that even when the cmdlet knows how to do something, that doesn't mean the particular provider you're working with will support that operation.

5.3 **Understanding how the filesystem is like other data stores**

The filesystem is a model for other forms of storage. For example, figure 5.2 shows the Windows Registry Editor.

The Registry is laid out much like the filesystem with folders (registry keys), files (registry values), and so on. It's this broad similarity that makes the filesystem the perfect model, which is why PowerShell connects to data stores as *drives*, exposing *items* and *item properties*. But this similarity takes you only so far: When you dig into the details, the various forms of storage *are* quite different. That's why the various `item` cmdlets support such a broad range of functionality, and why not every bit of functionality will work with every possible form of storage.

5.4 **Navigating the filesystem**

Another cmdlet you need to know when working with providers is `Set-Location`. It's what you use to change the shell's current location to a different container-type item, such as a folder:

```
PS C:\> Set-Location -Path C:\Windows
PS C:\Windows>
```

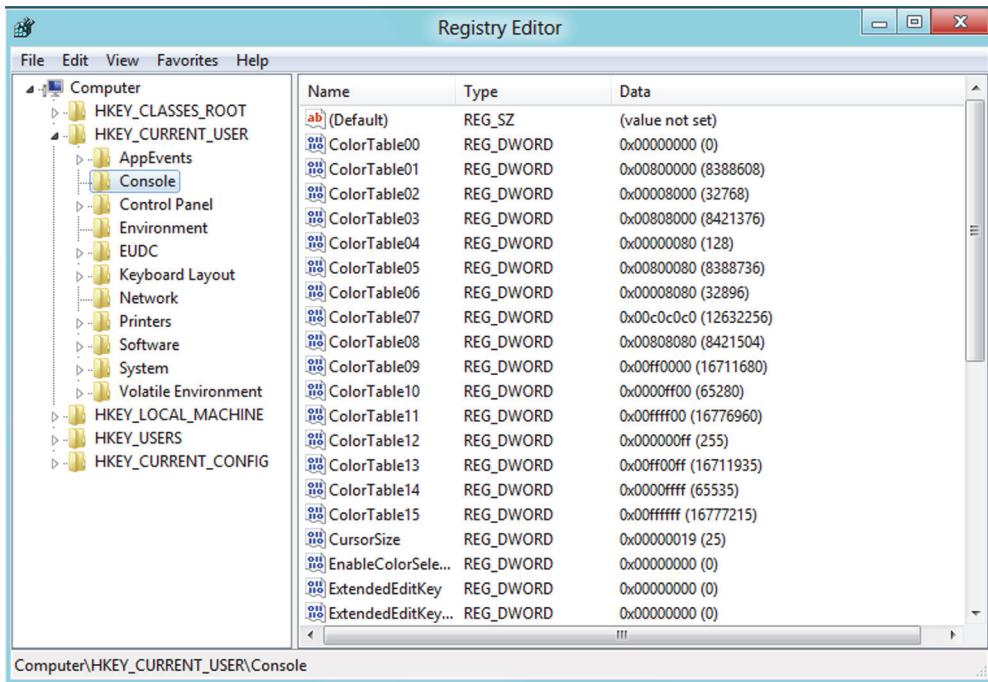

Figure 5.2 The Registry and the filesystem have the same kind of hierarchical storage.

You're probably more familiar with this command's alias, `Cd`, which corresponds to the `Change Directory` command from `Cmd.exe`:

```
PS C:\Windows> cd 'C:\Program Files'
PS C:\Program Files>
```

Here we use the alias and pass the desired path as a positional parameter.

Drives on non-Windows operating systems

macOS and Linux don't use *drives* to refer to discrete attached storage devices. Instead, the entire operating system has a single root, represented by a slash (in PowerShell, a backslash is also accepted). But PowerShell still provides PSDrives in non-Windows operating systems. Try running `Get-PSDrive` to see what's available.

One of the trickier tasks in PowerShell is creating new items. For example, how do you create a new directory? Try running `New-Item` and you'll get an unexpected prompt:

```
PS C:\users\donjones\Documents> New-Item testFolder
Type:
```

Remember, the `New-Item` cmdlet is generic—it doesn't know you want to create a folder. It can create folders, files, registry keys, and much more, but you have to tell it the type of item you want to create:

```
PS C:\users\donjones\Documents> new-item testFolder
Type: directory

    Directory: C:\users\donjones\Documents
Mode           LastWriteTime      Length Name
----           -----          ----- 
d---           3/29/2016   10:43 AM        testFolder
```

PowerShell does include a `mkdir` command, which most people think is an alias to `New-Item`. But using `mkdir` doesn't require you to enter a type:

```
PS C:\users\donjones\Documents> mkdir test2

    Directory: C:\users\donjones\Documents
Mode           LastWriteTime      Length Name
----           -----          ----- 
d---           3/29/2016   10:44 AM        test2
```

What gives? It turns out that `mkdir` is a function, not an alias. Internally, it still uses `New-Item`, but the function adds the `-Type Directory` parameter for you, making `mkdir` behave more like its Cmd.exe predecessor. Keeping this and other little details in mind can help you as you work with providers, because then you know that not every provider is the same, and that the `item` cmdlets are generic and sometimes need a bit more information than you might think at first.

5.5 Using wildcards and literal paths

Most of the `item` cmdlets include a `-Path` property, and by default that property accepts wildcards. Looking at the full help for `Get-ChildItem`, for example, reveals the following:

```
-Path <String[]>
  Specifies a path to one or more locations. Wildcards are permitted. The default location is the current directory (..).
  Required?           false
  Position?          1
  Default value       Current directory
  Accept pipeline input? true (ByValue, ByPropertyName)
  Accept wildcard characters? True
```

The `*` wildcard stands in for zero or more characters, whereas the `?` wildcard stands in for any single character. You've doubtless used this time and time again, probably with the `Dir` alias of `Get-ChildItem`:

```
PS C:\Windows> dir *.exe
Directory: C:\Windows
```

Mode	LastWriteTime	Length	Name

The wildcard characters listed in the preceding example are the same ones that Microsoft's filesystems—going all the way back to MS-DOS—have always used. Because those are special wildcard characters, they're not permitted in the names of files and folders. But in PowerShell, the filesystem isn't the only form of storage in use. In most other stores, * and ? are perfectly legal characters for item names. In the Registry, for example, you'll find a few values with names that include ?. This presents a problem: When you use * or ? in a path, is PowerShell supposed to treat it as a wildcard character or as a literal character? If you look for items named Windows?, do you want the item with Windows? as its name, or do you want ? treated as a wildcard, giving you items such as Windows7 and Windows8 instead?

PowerShell's solution is to provide an alternate `-LiteralPath` parameter. This parameter doesn't accept wildcards:

```
-LiteralPath <String[]>
    Specifies a path to one or more locations. Unlike the Path
    parameter, the value of the LiteralPath parameter is used exactly
    as it is typed. No characters are interpreted as wildcards. If
    the path includes escape characters, enclose it in single
    quotation marks. Single quotation marks tell Windows PowerShell
    not to interpret any characters as escape sequences.
    Required?          true
    Position?         named
    Default value
    Accept pipeline input?   true (ByValue, ByPropertyName)
    Accept wildcard characters? False
```

When you want * and ? taken literally, you use `-LiteralPath` instead of the `-Path` parameter. Note that `-LiteralPath` isn't positional; if you plan to use it, you have to type `-LiteralPath`. If you provide a path in the first position (such as *.exe in our first example), it'll be interpreted as being for the `-Path` parameter. Wildcards are also treated as such.

5.6 Working with other providers

One of the best ways to get a feel for these other providers, and how the various item cmdlets work, is to play with a PSDrive that isn't the filesystem. Of the providers built into PowerShell, the Registry is probably the best example to work with (in part

because it's available on every system). Our goal is to turn off the Aero Peek feature in Windows.

Start by changing to the HKEY_CURRENT_USER portion of the Registry, exposed by the HKCU: drive:

```
PS C:\> set-location -Path hkcu:
```

Next, navigate to the right portion of the Registry:

```
PS HKCU:\> set-location -Path software
PS HKCU:\software> get-childitem

    Hive: HKEY_CURRENT_USER\software
Name          Property
----          -----

DWM            Composition      : 1
                EnableAeroPeek : 1
                AlwaysHibernateThumbnails : 0
                ColorizationColor   :
                3226847725
                ColorizationColorBalance : 72
                ColorizationAfterglow   :
                3226847725
                ColorizationAfterglowBalance : 0
                ColorizationBlurBalance : 28
                ColorizationGlassReflectionIntensity : 50
                ColorizationOpaqueBlend  : 0
                ColorizationGlassAttribute : 0

Roaming
Shell
TabletPC
Windows Error Reporting        Disabled      : 0
                                MaxQueueCount : 50
                                DisableQueue  : 0
                                LoggingDisabled : 0
                                DontSendAdditionalData : 0
                                ForceQueue    : 0
                                DontShowUI    : 0
                                ConfigureArchive : 1
                                MaxArchiveCount : 500
                                DisableArchive  : 0
                                LastQueuePesterTime : 129773462733828600

```

Note the `EnableAeroPeek` Registry value. Let's change it to 0:

```
PS HKCU:\software\microsoft\Windows> Set-ItemProperty -Path dwm -PSPROPERTY
➥ EnableAeroPeek -Value 0
```

You also could have used the `-Name` parameter instead of `-PSPROPERTY`.

Let's check it again to make sure the change "took":

```
PS HKCU:\software\microsoft\Windows> Get-ChildItem

Hive: HKEY_CURRENT_USER\software\microsoft\Windows
Name                           Property
----                           -----
CurrentVersion
DWM                            Composition      : 1
                                EnableAeroPeek : 0
                                AlwaysHibernateThumbnails : 0
                                ColorizationColor   :
                                3226847725
                                ColorizationColorBalance : 72
                                ColorizationAfterglow   :
                                3226847725
                                ColorizationAfterglowBalance : 0
                                ColorizationBlurBalance  : 28
                                ColorizationGlassReflectionIntensity : 50
                                ColorizationOpaqueBlend  : 0
                                ColorizationGlassAttribute : 0
Roaming
Shell
TabletPC
Windows Error Reporting        Disabled       : 0
                                MaxQueueCount  : 50
                                DisableQueue   : 0
                                LoggingDisabled : 0
                                DontSendAdditionalData : 0
                                ForceQueue    : 0
                                DontShowUI    : 0
                                ConfigureArchive : 1
                                MaxArchiveCount : 500
                                DisableArchive  : 0
                                LastQueuePesterTime : 129773462733828600
```

Mission accomplished! Using these same techniques, you should be able to work with any provider that comes your way.

5.7 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.
This lab is designed only for Windows operating systems.

Complete the following tasks from a PowerShell prompt:

- In the Registry, go to `HKEY_CURRENT_USER\software\microsoft\Windows\currentversion\explorer`. Locate the `Advanced` key, and set its `DontPrettyPath` property to 1.

- 2 Create a new directory called C:\Labs.
- 3 Create a zero-length file named C:\Labs\Test.txt (use New-Item).
- 4 Is it possible to use Set-Item to change the contents of C:\Labs\Test.txt to TESTING? Or do you get an error? If you get an error, why?
- 5 Using the Environment provider, display the value of the system environment variable %TEMP%.
- 6 What are the differences between the -Filter, -Include, and -Exclude parameters of Get-ChildItem?

5.8 Further exploration

You'll find that providers are used for other software packages, including Internet Information Server (IIS), SQL Server, and even Active Directory. In most cases, those products' developers chose to use providers because their software is dynamically extensible. They couldn't know in advance what features would be installed for their products, so they couldn't write a static set of commands. Providers enable developers to expose dynamic structures in a consistent fashion, which lets the IIS and SQL Server teams, in particular, choose to use a combination of cmdlets and providers.

If you have access to these products (for IIS, you need v7.5 or later; for SQL Server, we suggest using SQL Server 2012 or later), spend some time exploring their provider models. See how the product teams have arranged the structure of their "drives," and how you can use the cmdlets covered in this chapter to review and change configuration settings and other details.

5.9 Lab answers

- 1 cd HKCU:\software\microsoft\Windows\currentversion\explorer
cd advanced
Set-ItemProperty -Path . -Name DontPrettyPath -Value 1
- 2 You can use either the mkdir function:
mkdir c:\labs
or the New-Item cmdlet:
new-item -path C:\Labs -ItemType Directory
- 3 New-Item -path c:\labs -Name test.txt -ItemType file
- 4 The filesystem provider doesn't support this action.
- 5 Either of these commands works:
Get-item env:temp
Dir env:temp
- 6 Include and Exclude must be used with -Recurse or if querying a container. Filter uses the PSProvider's filter capability, which not all providers support. For example, you could use DIR -filter in the filesystem but not in the Registry—although you could use DIR -include in the Registry to achieve almost the same type of filtering result.

The pipeline: connecting commands

In chapter 4, you learned that running commands in PowerShell is the same as running commands in any other shell: You type a command name, give it parameters, and hit Enter. What makes PowerShell special isn't the way it runs commands, but the way it allows multiple commands to be connected to each other in powerful, one-line sequences.

6.1 *Connecting one command to another: less work for you*

PowerShell connects commands to each other by using a *pipeline*. The pipeline provides a way for one command to pass, or *pipe*, its output to another command, allowing that second command to have something to work with.

You've already seen this in action in commands such as `Dir | More`. You're piping the output of the `Dir` command into the `More` command; the `More` command takes that directory listing and displays it one page at a time. PowerShell takes that same piping concept and extends it to greater effect.

PowerShell's use of a pipeline may seem similar at first to the way UNIX and Linux shells work. Don't be fooled, though. As you'll come to realize over the next few chapters, PowerShell's pipeline implementation is much richer and more modern.

6.2 Exporting to a CSV or an XML file

Run a simple command. Here are a few suggestions:

- Get-Process (or gps; this should work on macOS and Linux too)
- Get-Service (or gsv; only on Windows)
- Get-EventLog Security -newest 100 (only on Windows)

We picked these commands because they're easy, straightforward commands. We used parentheses to give you the aliases for Get-Process and Get-Service. For Get-EventLog, which works only on Windows, we specified its mandatory parameter as well as the -newest parameter (which shows you that the command won't take too long to execute).

TRY IT NOW Go ahead and choose the commands you want to work with. We use Get-Process for the following examples; you can stick with one of the three we've listed, or switch between them to see the differences in the results.

What do you see? When we run Get-Process, a table with several columns of information appears on the screen (see figure 6.1).

Handles	NPM(K)	PM(K)	WS(K)	VM(M)	CPU(s)	Id	ProcessName
45	5	564	2076	18	0.00	1352	coherence

1071	44	11628	13988	134	3.17	932	svchost

Figure 6.1 The output of Get-Process is a table with several columns of information.

It's great to have that information on the screen, but that isn't all you might want to do with the information. For example, if you want to make charts and graphs of memory and CPU utilization, you might want to export the information into a comma-separated values (CSV) file that could be read into an application such as Microsoft Excel.

6.2.1 Exporting to CSV

Exporting to a file is where the pipeline and a second command come in handy:

```
Get-Process | Export-Csv procs.csv
```

Similar to piping `Dir` to `More`, we've piped our processes to `Export-Csv`. That second cmdlet has a mandatory positional parameter that we've used to specify the output filename. Because `Export-Csv` is a native PowerShell cmdlet, it knows how to translate the table usually generated by `Get-Process` into a standard CSV file.

Go ahead and open the file in Windows Notepad to see the results, as shown in figure 6.2:

```
Notepad procs.csv
```

The object type

Properties become column headings

Each object is a single line of data

```
PS C:\> get-process | export-csv c:\procs.csv
PS C:\> notepad .\procs.csv
PS C:\>
```

Figure 6.2 Viewing the exported CSV file in Windows Notepad

The first line of the file is a comment, preceded by a # character, and it identifies the kind of information that's included in the file. In figure 6.2, it's `System.Diagnostics.Process`, which is the under-the-hood name that Windows uses to identify the information related to a running process. The second line contains column headings, and the subsequent lines list the information for the various processes running on the computer.

You can pipe the output of almost any `Get-` cmdlet to `Export-CSV` and get excellent results. You may also notice that the CSV file contains a great deal more information than what's typically shown on the screen. That's deliberate. The shell knows it can't possibly fit all of that information on the screen, so it uses a configuration file, supplied by Microsoft, to select the most important information for onscreen display. In later chapters, we'll show you how to override that configuration to display whatever you want.

Once the information is saved into a CSV file, you can easily email it to colleagues and ask them to view it from within PowerShell. To do this, they'd import the file:

```
Import-CSV procs.csv
```

The shell would read in the CSV file and display the process information. It wouldn't be based on live information, but it would be a snapshot from the exact point in time that you created the CSV file.

6.2.2 **Exporting to XML**

What if CSV files aren't what you need? PowerShell also has an `Export-CliXML` cmdlet, which creates a generic command-line interface (CLI) Extensible Markup Language (XML) file. CliXML is unique to PowerShell, but any program capable of understanding XML can read it. You'll also have a matching `Import-CliXML` cmdlet. Both the import and export cmdlets (such as `Import-CSV` and `Export-CSV`) expect a filename as a mandatory parameter.

TRY IT NOW Try exporting such things as services, processes, or event log entries to a CliXML file. Make sure you can reimport the file, and try opening the resulting file in Notepad and Internet Explorer to see how each application displays the information.

Does PowerShell include any other import or export commands? You could find out by using the `Get-Command` cmdlet and specifying a `-verb` parameter with either `Import` or `Export`.

TRY IT NOW See if PowerShell comes with any other import or export cmdlets. You may want to repeat this check after you load new commands into the shell—something you'll do in the next chapter.

6.2.3 Comparing files

Both CSV and CliXML files can be useful for persisting snapshots of information, sharing those snapshots with others, and reviewing those snapshots at a later time. In fact, `Compare-Object` has a great way of using them. It has an alias, `Diff`, which we'll use.

First, run `help diff` and read the help for this cmdlet. We want you to pay attention to three parameters in particular: `-ReferenceObject`, `-DifferenceObject`, and `-Property`.

`Diff` is designed to take two sets of information and compare them to each other. For example, imagine that you run `Get-Process` on two computers that are sitting side by side. The computer that's configured exactly the way you want is on the left and is the *reference computer*. The computer on the right might be the same, or it might be somewhat different; it's the *difference computer*. After running the command on each, you're staring at two tables of information, and your job is to figure out whether any differences exist between the two.

Because these are processes that you're looking at, you're always going to see differences in things like CPU and memory utilization numbers, so we'll ignore those columns. In fact, focus on the `Name` column, because we want to see whether the *difference computer* contains any additional, or any fewer, processes than the *reference computer*. It might take you a while to compare all of the process names from both tables, but you don't have to—that's exactly what `Diff` will do for you.

Let's say you sit down at the reference computer and run this:

```
Get-Process | Export-Clixml reference.xml
```

We prefer using CliXML rather than CSV for comparisons like this, because CliXML can hold more information than a flat CSV file. You then transport that XML file to the difference computer, and run this command:

```
Diff -reference (Import-Clixml reference.xml)
    -difference (Get-Process) -property Name
```

Because the previous step is a bit tricky, we'll explain what's happening:

- As in math, parentheses in PowerShell control the order of execution. In the previous example, they force `Import-Clixml` and `Get-Process` to run before `Diff` runs. The output from `Import-CLI` is fed to the `-reference` parameter, and the output from `Get-Process` is fed to the `-difference` parameter.

The parameter names are `-referenceObject` and `-differenceObject`; keep in mind that you can abbreviate parameter names by typing enough of their names for the shell to be able to figure out which one you want. In this case, `-reference` and `-difference` are more than enough to uniquely identify these parameters. We probably could have shortened them even further to something like `-ref` and `-diff`, and the command would still have worked.

- Rather than comparing the two complete tables, `Diff` focuses on the `Name`, because we gave it the `-property` parameter. If we hadn't, it would think that

every process is different because the values of columns such as VM, CPU, and PM are always going to be different.

- The result is a table telling you what's different. Every process that's in the reference set, but not in the difference set, will have a <= indicator (which indicates that the process is present only on the left side). If a process is on the difference computer but not the reference computer, it'll have a => indicator instead. Processes that match across both sets aren't included in the Diff output.

TRY IT NOW Go ahead and try this. If you don't have two computers, start by exporting your current processes to a CliXML file, as shown in the previous example. Then start some additional processes, such as Notepad, Windows Paint, or Solitaire. Your computer will become the difference computer (on the right), whereas the CliXML file will still be the reference set (on the left).

Here's the output from our test:

```
PS C:\> diff -reference (import-clixml reference.xml) -difference
➥ (get-process) -property name
```

name	SideIndicator
---	-----
calc	=>
mspaint	=>
notepad	=>
conhost	<=
powershell_ise	<=

This is a useful management trick. If you think of those reference CliXML files as configuration baselines, you can compare any current computer to that baseline and get a difference report. Throughout this book, you'll discover more cmdlets that can retrieve management information, all of which can be piped into a CliXML file to become a baseline. You can quickly build a collection of baseline files for services, processes, operating system configuration, users and groups, and much more, and then use those at any time to compare the current state of a system to that baseline.

TRY IT NOW For fun, try running the Diff command again, but leave off the -property parameter entirely. See the results? Every single process is listed, because values such as PM, VM, and so forth have all changed, even though they're the same processes. The output also isn't as useful, because it displays each process's type name and process name.

By the way, you should know that Diff generally doesn't do well at comparing text files. Although other operating systems and shells have a Diff command that's explicitly intended for comparing text files, PowerShell's Diff command works differently. You'll see how differently in this chapter's concluding lab.

NOTE If it seems as though you're using Get-Process, Get-Service, and Get-EventLog often, well, that's on purpose. We guarantee you have access to those cmdlets because they're native to PowerShell and don't require an

add-in such as Exchange or SharePoint. That said, the skills you’re learning apply to every cmdlet you’ll ever need to run, including those that ship with Exchange, SharePoint, SQL Server, and other server products. Chapter 26 covers these access details, but for now, focus on *how* to use these cmdlets rather than what the cmdlets are accomplishing. We’ll work in some other representative cmdlets at the right time.

6.3 Piping to a file or a printer

Whenever you have nicely formatted output—for example, the tables generated by Get-Service or Get-Process—you may want to preserve that in a file or even on paper. Normally, cmdlet output is directed to the screen, which PowerShell refers to as the *host*, but you can change where that output goes. We’ve already showed you one way to do so:

```
Dir > DirectoryList.txt
```

The `>` character is a shortcut added to PowerShell to provide syntactic compatibility with the older Cmd.exe shell. In reality, when you run that command, PowerShell does the following under the hood:

```
Dir | Out-File DirectoryList.txt
```

You can run that same command on your own, instead of using the `>` syntax. Why would you do so? Because `Out-File` also provides additional parameters that let you specify alternative character encodings (such as UTF-8 or Unicode), append content to an existing file, and so forth. By default, the files created by `Out-File` are 80 columns wide, which means sometimes PowerShell might alter command output to fit within 80 characters. That alteration might make the file’s contents appear different than when you run the same command on the screen. Read `Out-File`’s help file and see if you can spot a parameter that would let you change the output file width to something other than 80 characters.

TRY IT NOW Don’t look here for the answer—open up that help file and see what you can find. We guarantee you’ll spot the right parameter in a few moments.

PowerShell has a variety of `Out-` cmdlets. One is called `Out-Default`, and it’s the one the shell uses when you don’t specify a different `Out-` cmdlet. If you run this

```
Dir
```

you’re technically running this:

```
Dir | Out-Default
```

even if you don’t realize it. `Out-Default` does nothing more than direct content to `Out-Host`, which means you’re running this:

```
Dir | Out-Default | Out-Host
```

without realizing it. `Out-Host` displays information on the screen. What other `Out-` cmdlets can you find?

TRY IT NOW Time to investigate other `Out-` cmdlets. To get started, try using the `Help` command and wildcards such as `Help Out*`. Another option is to use the `Get-Command` in the same way, such as `Get-Command Out*`. Or you could specify the `-verb` parameter: `Get-Command -verb Out`. What did you come up with?

`Out-Printer` is probably one of the most useful of the remaining `Out-` cmdlets, although it's available only on Windows. `Out-GridView` is also neat, but it requires that you have Microsoft .NET Framework v3.5 and the Windows PowerShell ISE installed, which isn't the case by default on server and non-Windows operating systems. If you do have those installed, try running `Get-Service | Out-GridView` to see what happens. `Out-Null` and `Out-String` have specific uses that we won't get into right now, but you're welcome to read their help files and look at the examples included in those files.

6.4 Converting to HTML

Want to produce HTML reports? Well, this isn't available on other operating systems (at the time of writing this book). But it's easy on Windows: Pipe your command to `ConvertTo-HTML`. This command produces well-formed, generic HTML that displays in any web browser. It's plain looking, but you can reference a Cascading Style Sheets (CSS) file to specify more-attractive formatting if desired. Notice that this command doesn't require a filename:

```
Get-Service | ConvertTo-HTML
```

TRY IT NOW Make sure that you run that command yourself—we want you to see what it does before you proceed.

In the PowerShell world, the verb `Export` implies that you're taking data, converting it to some other format, and saving that other format in some kind of storage, such as a file. The verb `ConvertTo` implies only a portion of that process: the conversion to a different format, but not saving it into a file. When you ran the preceding command, you got a screen full of HTML, which probably wasn't what you wanted. Stop for a second: Can you think of how you'd get that HTML into a text file on disk?

TRY IT NOW If you can think of a way, go ahead and try it before you read on.

This command does the trick:

```
Get-Service | ConvertTo-HTML | Out-File services.html
```

See how connecting more and more commands allows you to have increasingly powerful command lines? Each command handles a single step in the process, and the entire command line as a whole accomplishes a useful task.

PowerShell ships with other ConvertTo- cmdlets, including ConvertTo-CSV and ConvertTo-XML. As with ConvertTo-HTML, these don't create a file on disk; they translate command output into CSV or XML, respectively. You could pipe that converted output to Out-File to then save it to disk, although it would be shorter to use Export-CSV or Export-CliXML, because those do both the conversion and the saving.

Above and beyond

Time for a bit more useless background information, although in this case it's the answer to a question that many students often ask us: Why would Microsoft provide both Export-CSV and ConvertTo-CSV, as well as two nearly identical cmdlets for XML?

In certain advanced scenarios, you might not want to save the data to a file on disk. For example, you might want to convert data to XML and then transmit it to a web service or some other destination. By having distinct ConvertTo- cmdlets that don't save to a file, you have the flexibility to do whatever you want.

6.5 Using cmdlets that modify the system: killing processes and stopping services

Exporting and converting aren't the only reasons you might want to connect two commands together. For example, consider—but *please don't run*—this command:

```
Get-Process | Stop-Process
```

Can you imagine what that command would do? We'll tell you: Crash your computer. It would retrieve every process and then start trying to end each one of them. It would get to a critical process, such as the Local Security Authority, and your computer would probably crash with the famous Blue Screen of Death (BSOD). If you're running PowerShell inside a virtual machine and want to have a little fun, go ahead and try running that command.

The point is that cmdlets with the same noun (in this case, Process) can often pass information among each other. Typically, you'd specify the name of a specific process rather than trying to stop them all:

```
Get-Process -name Notepad | Stop-Process
```

Services offer something similar: The output from Get-Service can be piped to cmdlets such as Stop-Service, Start-Service, Set-Service, and so forth.

As you might expect, specific rules limit which commands can connect to each other. For example, if you look at a command sequence such as Get-ADUser | New-SQLDatabase, you probably wouldn't expect it to do anything sensible (although it might well do something nonsensical). In chapter 7, we'll dive into the rules that govern how commands can connect to each other.

We'd like you to know one more thing about cmdlets such as `Stop-Service` and `Stop-Process`. These cmdlets modify the system in some fashion, and all cmdlets that modify the system have an internally defined *impact level*. The cmdlet's creator sets this impact level and it can't be changed. The shell has a corresponding `$ConfirmPreference` setting, which is set to `High` by default. Type the following setting name to see your shell's setting:

```
PS C:\> $confirmPreference
High
```

Here's how it works: When a cmdlet's internal impact level is equal to or higher than the shell's `$ConfirmPreference` setting, the shell will automatically ask, "Are you sure?" when the cmdlet does whatever it's trying to do. If you used a virtual machine to try the crash-your-computer command we mentioned earlier, you probably were asked, "Are you sure?" for each process. When a cmdlet's internal impact level is less than the shell's `$ConfirmPreference` setting, you don't automatically get the "Are you sure?" prompt.

But you can force the shell to ask you whether you're sure:

```
Get-Service | Stop-Service -confirm
```

You just add the `-confirm` parameter to the cmdlet. This should be supported by any cmdlet that makes some kind of change to the system, and it'll show up in the help file for the cmdlet if it's supported.

A similar parameter is `-whatif`. This is supported by any cmdlet that supports `-confirm`. The `-whatif` parameter isn't triggered by default, but you can specify it whenever you want to:

```
PS C:\> get-process | stop-process -whatif
What if: Performing operation "Stop-Process" on Target "conhost (1920)"
".
What if: Performing operation "Stop-Process" on Target "conhost (1960)"
".
What if: Performing operation "Stop-Process" on Target "conhost (2460)"
".
What if: Performing operation "Stop-Process" on Target "csrss (316)".
```

This tells you what the cmdlet would have done, without letting the cmdlet do it. It's a useful way to preview what a potentially dangerous cmdlet would have done to your computer, to make certain that you want to do that.

6.6 Common points of confusion

One common point of confusion in PowerShell revolves around the `Export-CSV` and `Export-CliXML` commands. Both commands, technically speaking, create text files. The output of either command can be viewed in Notepad, as shown in figure 6.2. But you have to admit that the text is definitely in a special kind of format—either in CSV or XML.

The confusion tends to set in when someone is asked to read these files back into the shell. Do you use `Get-Content` (or its aliases, `Type` or `Cat`)? For example, suppose you do this:

```
PS C:\> get-eventlog -LogName security -newest 5 | export-csv events.csv
```

Now, try reading that back in by using `Get-Content`:

```
PS C:\> Get-Content .\events.csv

#TYPE System.Diagnostics.EventLogEntry#security/Microsoft-Windows-Security
-Auditing/4797
"EventID","MachineName","Data","Index","Category","CategoryNumber","EntryType",
"Message","Source","ReplacementStrings","InstanceId","TimeGenerated",
"TimeWritten","UserName","Site","Container"
"4797","DONJONES1D96","System.Byte[]","263","(13824)","13824","SuccessAudit",
"An attempt was made to query the existence of a blank password for an
account.
Subject:
    Security ID:          S-1-5-21-87969579-3210054174-450162487-100
    Account Name:         donjones
    Account Domain:       DONJONES1D96
    Logon ID:             0x10526
Additional Information:
    Caller Workstation:   DONJONES1D96
    Target Account Name: Guest
    Target Account Domain: DONJONES1D96", "Microsoft-Windows-Security-
Auditing
", "System.String[]","4797","3/29/2012 9:43:36 AM","3/29/2012 9:43:36 AM", ,
,
"4616","DONJONES1D96","System.Byte[]","262","(12288)","12288","SuccessAudit",
"The system time was changed.
```

We truncated the preceding output, but there's a lot more of the same. Looks like garbage, right? You're looking at the raw CSV data. The command didn't try to interpret, or *parse*, the data at all. Contrast that with the results of `Import-Csv`:

```
PS C:\> import-csv .\events.csv

EventID      : 4797
MachineName  : DONJONES1D96
Data         : System.Byte[]
Index        : 263
Category     : (13824)
CategoryNumber: 13824
EntryType    : SuccessAudit
Message      : An attempt was made to query the existence of a
                blank password for an account.
Subject:
    Security ID:          S-1-5-21-87969579-3210054174-450162487-1001
    Account Name:         donjones
    Account Domain:       DONJONES1D96
    Logon ID:             0x10526
```

```
Additional Information:  
    Caller Workstation:      DONJONES1D96  
    Target Account Name:     Guest  
    Target Account Domain:   DONJONES1D96  
Source          : Microsoft-Windows-Security-Auditing  
ReplacementStrings : System.String[]  
InstanceId       : 4797  
TimeGenerated    : 3/29/2012 9:43:36 AM  
TimeWritten      : 3/29/2012 9:43:36 AM  
UserName        :
```

Much nicer, right? The Import- cmdlets pay attention to what's in the file, attempt to interpret it, and create a display that looks more like the output of the original command (Get-EventLog, in this case). Typically, then, if you create a file with Export-CSV, you read it by using Import-CSV. If you create it by using Export-CliXML, you generally read it by using Import-CliXML. By using these commands in pairs, you get better results. Use Get-Content only when you're reading in a text file and don't want PowerShell attempting to parse the data—that is, when you want to work with the raw text.

6.7 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

We've kept this chapter's text slightly shorter because some of the examples probably took you a bit longer to complete, and because we want you to spend more time completing the following hands-on exercises. If you haven't already completed all of the "Try it now" tasks in this chapter, we strongly recommend that you do so before tackling these tasks:

- 1 Create two similar, but different, text files. Try comparing them by using Diff. Run something like this: Diff -reference (Get-Content File1.txt) -difference (Get-Content File2.txt). If the files have only one line of text that's different, the command should work.
- 2 What happens (on Windows) if you run Get-Service | Export-CSV services.csv | Out-File from the console? Why does that happen?
- 3 Apart from getting one or more services and piping them to Stop-Service, what other means does Stop-Service provide for you to specify the service or services you want to stop? Is it possible to stop a service without using Get-Service at all?
- 4 What if you want to create a pipe-delimited file instead of a comma-separated (CSV) file? You'd still use the Export-CSV command, but what parameters would you specify?
- 5 Is there a way to eliminate the # comment line from the top of an exported CSV file? That line typically contains type information, but what if you want to omit that from a particular file?

- 6 Export-CliXML and Export-CSV both modify the system because they can create and overwrite files. What parameter would prevent them from overwriting an existing file? What parameter would ask whether you were sure before proceeding to write the output file?
- 7 Windows maintains several regional settings, which include a default list separator. On U.S. systems, that separator is a comma. How can you tell Export-CSV to use the system's default separator rather than a comma?

TRY IT NOW After you've completed this lab, try to complete Review Lab 1, which you'll find in the appendix.

6.8 Lab answers

- 1 PS C:\> "I am the walrus" | out-file file1.txt
PS C:\> "I'm a believer" | out-file file2.txt
PS C:\> \$f1=get-content .\file1.txt
PS C:\> \$f2=Get-Content .\file2.txt
PS C:\> diff \$f1 \$f2

InputObject	SideIndicator
-----	-----
I'm a believer	=>
I am the walrus	<=
- 2 If you don't specify a filename with Out-File, you'll get an error. But even if you do, Out-File won't do anything because the file is created by Export-CSV.
- 3 Stop-Service can accept one or more service names as parameter values for the -Name parameter. For example, you could run this:
Stop-Service spooler
- 4 get-service | Export-Csv services.csv -Delimiter "|"
- 5 Use the -NoTypeInformation parameter with Export-CSV.
- 6 get-service | Export-Csv services.csv -noclobber
get-service | Export-Csv services.csv -confirm
- 7 get-service | Export-Csv services.csv -UseCulture

Adding commands

One of PowerShell's primary strengths is its extensibility. As Microsoft continues to invest in PowerShell, it develops more and more commands for products including Exchange Server, SharePoint Server, the System Center family, SQL Server, and so on. Typically, when you install these products' management tools, you also get a graphical management console of some kind and one or more extensions for Windows PowerShell.

7.1 How one shell can do everything

We know you're probably familiar with the graphical Microsoft Management Console (MMC), which is why we'll use it as an example of how PowerShell works. The two work similarly when it comes to extensibility, in part because the same Management Frameworks team within Microsoft develops both the MMC and PowerShell.

When you open a new, blank MMC console, it's largely useless. It can't do anything, because the MMC has little built-in functionality. To make it useful, you go to its File menu and select Add/Remove Snapins. In the MMC world, a *snap-in* is a tool, such as Active Directory Users and Computers, DNS Management, DHCP Administration, and so on. You can add as many snap-ins to your MMC as you like, and you can save the resulting console to make it easier to reopen that same set of snap-ins in the future.

Where do snap-ins come from? Once you've installed the management tools associated with a product such as Exchange Server, Forefront, or System Center, you'll find those products' snap-ins listed in the Add/Remove Snapins dialog box within the MMC. Most products also install their own preconfigured MMC console

files, which do nothing but load the basic MMC and preload a snap-in or two. You don’t have to use those preconfigured consoles if you don’t want to, because you can always open a blank MMC console and load the exact snap-ins you want. For example, the preconfigured Exchange Server MMC console doesn’t include the Active Directory Sites and Services snap-in, but you can easily create an MMC console that includes Exchange as well as Sites and Services.

PowerShell works in almost exactly the same way. Install the management tools for a given product (the option to install management tools is usually included in a product’s Setup menu—if you install a product such as Exchange Server on Windows 7, the management tools will often be the only thing Setup offers). Doing so will give you any related PowerShell extensions, and it may even create a product-specific management shell.

7.2 About product-specific “management shells”

These product-specific management shells have been a huge source of confusion. We want to clearly state that there’s only one Windows PowerShell. There isn’t a separate PowerShell for Exchange and Active Directory; it’s all a single shell.

Let’s take Active Directory as an example. On the Start menu of a Windows Server 2008 R2 domain controller, under Administrative Tools, you’ll find an icon for the Active Directory Module for Windows PowerShell. If you right-click that item and select Properties from the context menu, the first thing you should see is the Target field, which will be this:

```
%windir%\system32\WindowsPowerShell\v1.0\powershell.exe  
➥ -noexit -command import-module ActiveDirectory
```

This command runs the standard PowerShell.exe application and gives it a command-line parameter to run a specific command: `Import-Module ActiveDirectory`. The result is a copy of the shell that has the ActiveDirectory module preloaded. But we can think of no reason that you couldn’t open the “normal” PowerShell and run that same command yourself to get the same functionality.

The same holds true for almost every product-specific “management shell” you’ll find: Exchange, SharePoint, you name it. Examine the properties of those products’ Start menu shortcuts, and you’ll find that they open the normal PowerShell.exe and pass a command-line parameter to either import a module, add a snap-in, or load a preconfigured console file (and the console file is simply a list of snap-ins to load automatically).

SQL Server 2008 and SQL Server 2008 R2 are exceptions. Their “product-specific” shell, `Sqlps`, is a specially compiled version of PowerShell that runs only the SQL Server extensions. Properly called a *mini-shell*, Microsoft tried this approach for the first time in SQL Server. It was unpopular, and the company won’t be using that approach again: SQL Server 2012 uses PowerShell.

You're not constrained to working with the prespecified extensions. Once you open the Exchange management shell, you could run `Import-Module ActiveDirectory`, and provided the ActiveDirectory module was present on your computer, you'd add the Active Directory functionality to that shell. You could also open a standard PowerShell console and manually add whatever extensions you like.

As we stated earlier in this section, this has been a huge point of confusion for folks, including some who believed multiple versions of PowerShell existed that couldn't use each other's functionality. Several years ago, Don even got into an argument on his blog about it and had to ask members of the PowerShell team to step in and back him up. So trust us: You can have all the functionality you want inside a single shell, and the product-specific shell shortcuts in the Start menu don't in any way limit you or imply that special versions of PowerShell exist for those products.

7.3 Extensions: finding and adding snap-ins

PowerShell has two kinds of extensions: modules and snap-ins. We'll look at snap-ins first.

The proper name for a PowerShell snap-in is *PSSnapin*, which distinguishes these from snap-ins for the graphical MMS. PSSnapins were first created for PowerShell v1. A PSSnapin generally consists of one or more DLL files, accompanied by additional XML files that contain configuration settings and help text. PSSnapins have to be installed and registered in order for PowerShell to know they exist.

NOTE The PSSnapin concept is something Microsoft is moving away from, and you're likely to see fewer and fewer of them in the future. Internally, Microsoft is focusing on delivering extensions as modules.

You can get a list of available snap-ins by running `Get-PSSnapin -registered` from within PowerShell. On our computer, which is a domain controller that happens to have SQL Server 2008 installed, we see this:

```
PS C:\> get-pssnapin -registered

Name      : SqlServerCmdletSnapin100
PSVersion : 2.0
Description : This is a PowerShell snap-in that includes various SQL
              Server cmdlets.
Name      : SqlServerProviderSnapin100
PSVersion : 2.0
Description : SQL Server Provider
```

This tells us that we have two snap-ins installed and available, but not loaded. You can view a list of loaded snap-ins by running `Get-PSSnapin`. That list will include all of the core, automatically loaded snap-ins that contain PowerShell's native functionality.

To load a snap-in, run `Add-PSSnapin` and specify the name of the snap-in:

```
PS C:\> add-pssnapin sqlservercmdletsnapin100
```

As is often the case in PowerShell, you don't need to worry about getting uppercase and lowercase letters correct. The shell won't care.

Once a snap-in is loaded, you'll want to figure out what it added to the shell. A PSSnapin can add cmdlets, PSDrive providers, or both to the shell. To find out which cmdlets you've added, use `Get-Command` (or its alias, `Gcm`):

```
PS C:\> gcm -pssnapin sqlservercmdletsnapin100
CommandType      Name                Definition
-----          ----
Cmdlet          Invoke-PolicyEvaluation  Invoke-PolicyEvaluation...
Cmdlet          Invoke-Sqlcmd          Invoke-Sqlcmd [[-Query]...]
```

Here we've specified that only the commands from the `SqlServerCmdletSnapin100` snap-in be included in the output, and only two are listed. Yes, that's all SQL Server adds in that snap-in, but one of those is capable of executing Transact-SQL (T-SQL) commands. Because you can accomplish almost anything in SQL Server by executing a T-SQL command, the `Invoke-Sqlcmd` cmdlet makes it possible to do almost anything you might need to do in SQL Server.

To see whether the snap-in added any new PSDrive providers, run `Get-PSProvider`. You can't specify a snap-in with this cmdlet, so you'll have to be familiar with the providers that are already there, and scan through the list manually to spot anything new. Here are our results:

```
PS C:\> get-psprovider
Name            Capabilities        Drives
----          -----
WSMan           Credentials         {WSMan}
Alias           ShouldProcess     {Alias}
Environment     ShouldProcess     {Env}
FileSystem      Filter, ShouldProcess {C, A, D}
Function        ShouldProcess     {Function}
Registry        ShouldProcess, Transa... {HKLM, HKCU}
Variable        ShouldProcess     {Variable}
Certificate     ShouldProcess     {cert}
```

Doesn't look like anything new. We're not surprised, because the snap-in we loaded is named `SqlServerCmdletSnapin100`. If you recall, our list of available snap-ins also includes `SqlServerProviderSnapin100`, suggesting that the SQL Server team, for some reason, packaged its cmdlets and PSDrive provider separately. Let's try adding the second one:

```
PS C:\> add-pssnapin sqlserverprovidersnapin100
PS C:\> get-psprovider
Name            Capabilities        Drives
----          -----
WSMan           Credentials         {WSMan}
Alias           ShouldProcess     {Alias}
Environment     ShouldProcess     {Env}
```

FileSystem	Filter, ShouldProcess	{C, A, D}
Function	ShouldProcess	{Function}
Registry	ShouldProcess, Transa...	{HKLM, HKCU}
Variable	ShouldProcess	{Variable}
Certificate	ShouldProcess	{cert}
SqlServer	Credentials	{SQLSERVER}

Reviewing the previous output, we see that a SQLSERVER: drive has been added to our shell, powered by the SqlServer PSDrive provider. Adding this new drive means we can run `cd sqlserver:` to change to the SQLSERVER: drive, and presumably start exploring databases and stuff.

7.4 Extensions: finding and adding modules

PowerShell v3 (and v2) supports a second type of extension called a *module*. Modules are designed to be a little more self-contained and somewhat easier to distribute. Although they work similarly to PSsnapins, you do need to know a bit more about them in order to find and use them.

Modules don't require advanced registration. Instead, PowerShell automatically looks in a certain set of paths to find modules. The `PSModulePath` environment variable defines the paths where PowerShell expects modules to live:

```
PS C:\> get-content env:psmodulepath
→C:\Users\Administrator\Documents\WindowsPowerShell\Modules;C:\Windows
→\system32\WindowsPowerShell\v1.0\Modules\
```

As you can see in this example, there are two default locations: one in the operating system folder, where system modules live, and one in the Documents folder, where you can add any personal modules. If you're running even later versions of PowerShell, you might see additional locations that Microsoft is now using. You can also add a module from any other location, provided you know its full path.

NOTE `PSModulePath` isn't something you can modify within PowerShell; it's set as part of your Windows environment. You can change it in the System Control Panel, or you can set it via Group Policy. Some Microsoft or third-party products might also modify this variable.

The path is important in PowerShell v3. If you have modules located elsewhere, you should add their paths to the `PSModulePath` environment variable. Figure 7.1 shows how you do this from the Windows Control Panel, not from within PowerShell.

Why is the `PSModulePath` so important? Because with it, PowerShell can automatically locate all of the modules on your computer. After it finds your modules, PowerShell *autodiscovers* them. It will look to you as if all of your modules are loaded all of the time. Ask for help on a module, and you'll get it, without having to load it. Run any command you've found, and PowerShell will automatically load the module containing that command. PowerShell's `Update-Help` command also uses `PSModulePath` to discover what modules you have, and then it seeks updated help files for each one.

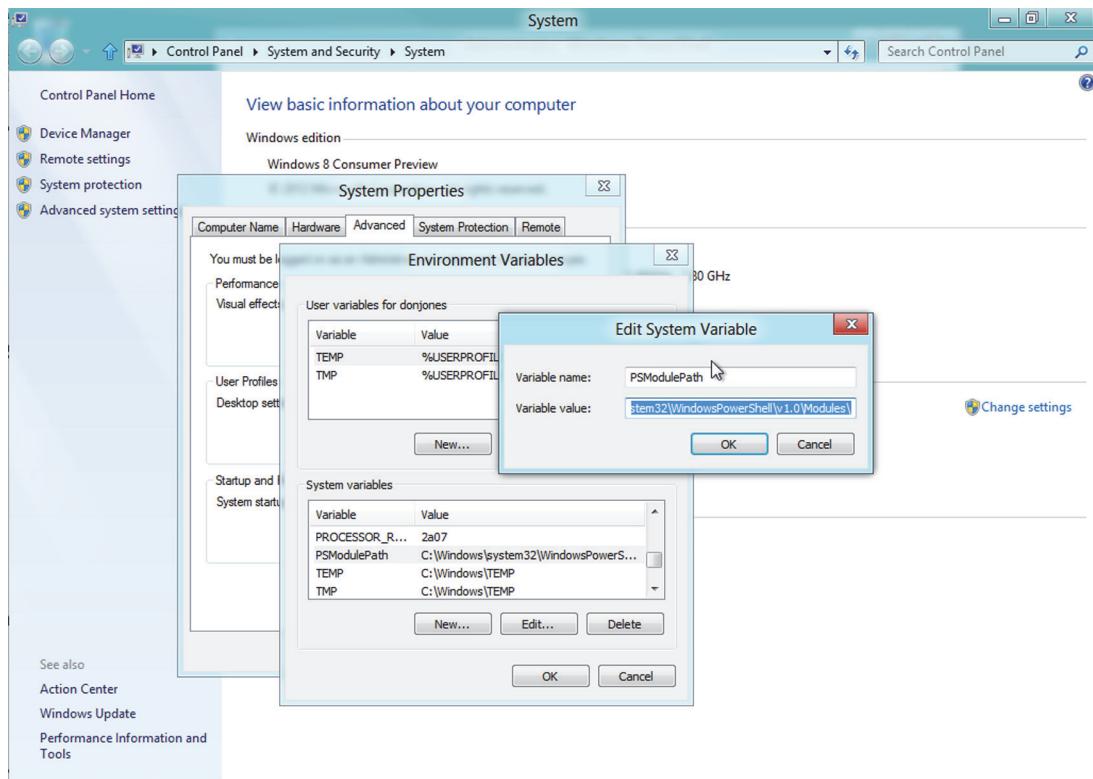

Figure 7.1 Changing the `PSModulePath` environment variable in Windows

For example, run `Get-Module | Remove-Module` to remove any loaded modules. Then run the following command (your results may differ slightly, depending on which specific version of Windows you're using):

```
PS C:\> help *network*
```

Name	Category	Module
---	-----	-----
Get-BCNetworkConfiguration	Function	BranchCache
Get-DtcNetworkSetting	Function	MsDtc
Set-DtcNetworkSetting	Function	MsDtc
Get-SmbServerNetworkInterface	Function	SmbShare
Get-SmbClientNetworkInterface	Function	SmbShare

As you can see, PowerShell discovers several commands (of the function variety) that have the word `network` in their name. You can then ask for help on one of these, even though you haven't loaded the module:

```
PS C:\> help Get-SmbServerNetworkInterface
```

NAME	
	Get-SmbServerNetworkInterface

SYNTAX

```
Get-SmbServerNetworkInterface [-CimSession <CimSession[]>]
[-ThrottleLimit <int>] [-AsJob] [<CommonParameters>]
```

If you want to, you can even run the command, and PowerShell will make sure the module is loaded for you. This autodiscovery and autoloading functionality is useful, helping you to find and use commands that aren't even present in the shell when you start.

TIP You can also use `Get-Module` to retrieve a list of modules available on a remote computer, and use `Import-Module` to load a remote module into your current PowerShell session. You'll learn how to do that in chapter 13.

PowerShell's module autodiscovery enables the shell to complete command names (using Tab in the console, or IntelliSense in the ISE), display help, and run commands, even for modules you haven't explicitly loaded into memory. These features make it worth the effort to keep `PSModulePath` complete and up-to-date.

What if a module isn't located in one of the paths referenced by `PSModulePath`? You'd need to run `Import-Module` and specify the complete path to the module, such as `C:\MyPrograms\Something\MyModule`.

If you have a Start menu shortcut for a product-specific shell—say, SharePoint Server—and you don't know where that product installed its PowerShell module, open the properties for the Start menu shortcut. As we showed you earlier in this chapter, the Target property of the shortcut will contain the `Import-Module` command used to load the module, and that will show you the module name and path.

Modules can also add PSDrive providers. You'd use the same technique you used for PSSnapins to identify any new providers: run `Get-PSPrinter`.

7.5 Command conflicts and removing extensions

Take a close look at the commands we added for both SQL Server and Active Directory. Notice anything special about the commands' names?

Most PowerShell extensions—Exchange Server being a notable exception—add a short prefix to the noun portion of their command names. `Get-ADUser`, for example, or `Invoke-SqlCmd`. These prefixes may seem awkward, but they're designed to prevent command conflicts.

For example, suppose you load two modules that each contain a `Get-User` cmdlet. With two commands having the same name and being loaded at the same time, which one will PowerShell execute when you run `Get-User`? The last one loaded, as it turns out. But the other command with the same name isn't inaccessible. To specifically run either command, you have to use a somewhat awkward naming convention that requires both the snap-in name and the command name. If one `Get-User` comes from a snap-in called `MyCoolPowerShellSnapin`, you have to run this:

```
MyCoolPowerShellSnapin\Get-User
```

That's a lot of typing, and it's why Microsoft suggests adding a product-specific prefix, such as `AD` or `SQL`, to the noun of each command. Adding prefixes helps prevent a conflict and helps make commands easier to identify and use.

If you do wind up with a conflict, you can always choose to remove one of the conflicting extensions. You run `Remove-PSSnapin` or `Remove-Module`, along with the snap-in or the module name, to unload an extension.

7.6 On non-Windows operating systems

If you're on Linux or macOS, some caveats apply to the foregoing discussion. For one, the `PSModulePath` environment variable, although it does exist, will point elsewhere. Make sure you check it to see where your particular computer is looking for modules.

Additionally, a lot of the modules already out in the world won't run. They may rely on functionality (for example, WMI) that doesn't exist on your computer, or they may have underlying dependencies (such as Active Directory connectivity) that haven't been made available for your operating system. But it works both ways: You'll probably find the odd PowerShell module that doesn't work on Windows, but instead works with specific Linux or macOS features. This emphasizes the line between PowerShell as a product, and all the things PowerShell can "touch."

7.7 Playing with a new module

Let's put your newfound knowledge to use. We'll assume that you're using the newest version of Windows (not macOS or Linux), and we want you to follow along with the commands we present in this section. More important, we want you to follow the process and the thinking that we'll explain, because this is how we teach ourselves to use new commands without rushing out and buying a new book for every product and feature that we run across. In the concluding lab for this chapter, we'll have you repeat this same process on your own, to learn about an entirely new set of commands.

Our goal is to clear the DNS name resolution cache on our computer. We have no idea whether PowerShell can even do this, so we start by asking the help system for a clue:

```
PS C:\> help *dns*
```

Name	Category	Module
----	-----	-----
dnsn	Alias	
Resolve-DnsName	Cmdlet	DnsClient
Clear-DnsClientCache	Function	DnsClient
Get-DnsClient	Function	DnsClient
Get-DnsClientCache	Function	DnsClient
Get-DnsClientGlobalSetting	Function	DnsClient
Get-DnsClientServerAddress	Function	DnsClient
Register-DnsClient	Function	DnsClient
Set-DnsClient	Function	DnsClient
Set-DnsClientGlobalSetting	Function	DnsClient
Set-DnsClientServerAddress	Function	DnsClient
Add-DnsClientNrptRule	Function	DnsClient

Get-DnsClientNrptPolicy	Function	DnsClient
Get-DnsClientNrptGlobal	Function	DnsClient
Get-DnsClientNrptRule	Function	DnsClient
Remove-DnsClientNrptRule	Function	DnsClient
Set-DnsClientNrptGlobal	Function	DnsClient
Set-DnsClientNrptRule	Function	DnsClient

Aha! As you can see, we have an entire DnsClient module on our computer. The previous list shows the Clear-DnsClientCache command, but we're curious about what other commands are available. To find out, we manually load the module and list its commands.

TRY IT NOW Follow along as we run these commands. If you don't have a DnsClient module on your computer, you're using an older version of Windows. Consider getting a newer version, or even a trial version that you can run inside a virtual machine, so that you can follow along.

```
PS C:\> import-module -Name DnsClient
PS C:\> get-command -Module DnsClient

Capability      Name
-----          ---
CIM             Add-DnsClientNrptRule
CIM             Clear-DnsClientCache
CIM             Get-DnsClient
CIM             Get-DnsClientCache
CIM             Get-DnsClientGlobalSetting
CIM             Get-DnsClientNrptGlobal
CIM             Get-DnsClientNrptPolicy
CIM             Get-DnsClientNrptRule
CIM             Get-DnsClientServerAddress
CIM             Register-DnsClient
CIM             Remove-DnsClientNrptRule
CIM             Set-DnsClient
CIM             Set-DnsClientGlobalSetting
CIM             Set-DnsClientNrptGlobal
CIM             Set-DnsClientNrptRule
CIM             Set-DnsClientServerAddress
Cmdlet          Resolve-DnsName
```

NOTE We could have asked for help on Clear-DnsClientCache or even run the command directly. PowerShell would have loaded the DnsClient module for us in the background. But because we're exploring, this approach lets us view the module's complete list of commands.

This list of commands looks more or less the same as the earlier list. Fine; let's see what the Clear-DnsClientCache command looks like:

```
PS C:\> help Clear-DnsClientCache

NAME
    Clear-DnsClientCache
```

SYNTAX

```
Clear-DnsClientCache [-CimSession <CimSession[]>] [-ThrottleLimit  
<int>] [-AsJob] [-WhatIf] [-Confirm] [<CommonParameters>]
```

Seems straightforward, and we don't see any mandatory parameters. Let's try running the command:

```
PS C:\> Clear-DnsClientCache
```

OK, no news is usually good news. Still, it'd be nice to see that the command did something. Let's try this instead:

```
PS C:\> Clear-DnsClientCache -verbose  
VERBOSE: The specified name resolution records cached on this machine will  
be removed.  
Subsequent name resolutions may return up-to-date information.
```

The `-verbose` switch is available for all commands, although not all commands do anything with it. In this case, we get a message indicating what's happening, which tells us the command did run.

7.8 **Profile scripts: preloading extensions when the shell starts**

Let's say you've opened PowerShell, and you've loaded several favorite snap-ins and modules. If you took that route, you'd be required to run one command for each snap-in or module you want to load, which can take a few minutes of typing if you have several of them. When you're done using the shell, you close its window. The next time you open a shell window, all of your snap-ins and modules are gone, and you have to run all those commands again to load them back. Horrible. There must be a better way.

We'll show you three better ways. The first involves creating a *console file*. This only memorizes PSSnapins that are loaded—it won't work with any modules you may have loaded. Start by loading in all of the snap-ins you want, and then run this command:

```
Export-Console c:\myshell.psc
```

Running the command creates a small XML file that lists the snap-ins you loaded into the shell.

Next, you want to create a new PowerShell shortcut somewhere. The target of that shortcut should be

```
%windir%\system32\WindowsPowerShell\v1.0\powershell.exe  
-noexit -psconsolefile c:\myshell.psc
```

When you use that shortcut to open a new PowerShell window, your console loads, and the shell automatically adds any snap-ins listed in that console file. Again, modules aren't included. What do you do if you have a mix of snap-ins and modules, or if you have some modules that you always want loaded?

TIP Keep in mind that PowerShell will autoload modules that are in one of the `PSModulePath` locations. You need to worry about the following steps only if you want to preload modules that aren't in one of the `PSModulePath` locations.

The answer is to use a *profile script*. We've mentioned those before, and we'll cover them in more detail in chapter 25, but for now follow these steps to learn how to use them on Windows:

- 1 In your Documents folder, create a new folder called WindowsPowerShell (no spaces in the folder name; it's different on non-Windows operating systems, but you can run `$profile` in the shell to see the correct path).
- 2 In the newly created folder, use Notepad to create a file named `profile.ps1`. When you save the file in Notepad, be sure to enclose the filename in quotation marks ("`profile.ps1`"). Using quotes prevents Notepad from adding a `.txt` filename extension. If that `.txt` extension gets added, this trick won't work.
- 3 In that newly created text file, type your `Add-PSSnapin` and `Import-Module` commands, listing one command per line in order to load your preferred snap-ins and modules.
- 4 Back in PowerShell, you need to enable script execution, which is disabled by default. Security consequences may result that we'll discuss in chapter 17, but for now we'll assume you're doing this in a standalone virtual machine, or on a standalone test computer, and that security is less of an issue. In the shell, run `Set-ExecutionPolicy RemoteSigned`. Note that the command works only if you're on Windows and run the shell as *Administrator*. It's also possible for a Group Policy object (GPO) to override this setting; you'll get a warning message if that's the case.
- 5 Assuming you haven't had any errors or warnings up to this point, close and reopen the shell. It automatically loads `profile.ps1`, executes your commands, and loads your favorite snap-ins and modules for you.

TRY IT NOW Even if you don't have a favorite snap-in or module yet, creating this simple profile is good practice. If nothing else, put the command `cd \` into the profile script, so that the shell always opens in the root of your system drive. But please don't do this on a computer that's part of your company's production network, because we haven't covered all of the security implications yet.

7.9 Getting modules from the internet

Microsoft introduced a new module called `PowerShellGet`, which makes it easier to search for, download, install, and update modules from online repositories. `PowerShellGet` is a lot like the package managers Linux admins love so much—`rpm`, `yum`, `apt-get`, and so on. Microsoft even runs an online *gallery*, or repository, called `PowerShell Gallery` (<http://powershellgallery.com>).

CAUTION *Microsoft runs* doesn't mean *Microsoft produces, verifies, and endorses*. The PowerShell Gallery contains community-contributed code, and you should use due caution before running someone else's code in your environment.

PowerShellGet ships with PowerShell v5 and later (although it may not be present on non-Windows operating systems at the outset), so if that's what you have installed (check \$PSVersionTable), you have it. <http://PowerShellGallery.com> contains a link to the PowerShellGet module, which you can download and install for Windows 7 Service Pack 1 and later, or Windows Server 2008 R2 Service Pack 1 and later. You do need a specific version of .NET Framework installed, and the download page includes that and other system requirements.

Using PowerShellGet is easy and can even be fun:

- Run Register-PSRepository to add the URL of a repository. <http://PowerShellGallery.com> is usually set up by default, but it's even possible to set up your own "gallery" internally for private use, and you'd use Register-PSRepository to point to it.
- Use Find-Module to find modules in repositories. You can use wildcards in names, specify tags, and have many other choices for narrowing the search results.
- Use Install-Module to download and install a module, after you've found it.
- Use Update-Module to make sure your local copy of a module is the latest version, and if it isn't, to download and install the latest.

PowerShellGet includes a bunch of other commands (<http://PowerShellGallery.com> links to the documentation), but these are the ones you'll start out using. For example, try installing PowerShellGet (if you're not running PowerShell v5) and installing Don's EnhancedHTML2 (there's a whole free book on <http://PowerShell.org>, *Creating HTML Reports in PowerShell*, that describes the module) or Jeff's ISEScriptingGeek module from PowerShell Gallery!

7.10 Common points of confusion

PowerShell newcomers frequently do one thing incorrectly when they start working with modules and snap-ins: They don't read the help. Specifically, they don't use the -example or -full switches when asking for help.

Frankly, looking at built-in examples is the best way to learn how to use a command. Yes, it can be a bit daunting to scroll through a list of hundreds of commands (Exchange Server, for example, adds well over 400 new commands), but using Help and Get-Command with wildcards should make it easier to narrow the list to whatever noun you think you're after. From there, *read the help!*

7.11 Lab

NOTE For this lab, you need a Windows 7, Windows Server 2008 R2, or later computer running PowerShell v3 or later.

As always, we're assuming that you have the latest version of Windows (client or server) on a computer or virtual machine to test with.

For this lab, you have only one task: Run the Networking troubleshooting pack. When you successfully do so, you'll be asked for an Instance ID. Hit Enter, run a Web Connectivity check, and ask for help connecting to a specific web page. Use www.pluralsight.com/browse/it-ops as your test URL. We hope you get a "No problems were detected" report, meaning you ran the check successfully.

To accomplish this task, you need to discover a command capable of getting a troubleshooting pack, and another capable of executing a troubleshooting pack. You also need to discover where the packs are located and how they're named. Everything you need to know is in PowerShell, and the help system will find it for you.

That's all the help you get!

7.12 Lab answers

Here's one way to approach this:

- `get-module *trouble* -list`
- `import-module TroubleShootingPack`
- `get-command -Module TroubleShootingPack`
- `help get-troubleshootingpack -full`
- `help Invoke-TroubleshootingPack -full`
- `dir C:\windows\diagnostics\system`
- `$pack=get-troubleshootingpack C:\windows\diagnostics\system\Networking`
- `Invoke-TroubleshootingPack $pack`
- `Enter`
- `1`
- `2`
- `https://www.pluralsight.com/browse/it-ops`

Objects: data by another name

We're going to do something a little different in this chapter. PowerShell's use of objects can be one of its most confusing elements, but at the same time it's also one of the shell's most critical concepts, affecting everything you do in the shell. We've tried various explanations over the years, and we've settled on a couple that each work well for distinctly different audiences. If you have programming experience and are comfortable with the concept of objects, we want you to skip to section 8.2. If you don't have a programming background, and haven't programmed or scripted with objects before, start with section 8.1 and read straight through the chapter.

8.1 What are objects?

Take a second to run `Get-Process` in PowerShell. You should see a table with several columns, but those columns barely scratch the surface of the wealth of information available about processes. Each process object also has a machine name, a main window handle, a maximum working set size, an exit code and time, processor affinity information, and a great deal more. You'll find more than 60 pieces of information associated with a process. Why does PowerShell show so few of them?

The simple fact is that *most* of the things PowerShell can access offer more information than will comfortably fit on the screen. When you run any command, such as `Get-Process`, `Get-Service`, or `Get-EventLog`, PowerShell constructs—entirely in memory—a table that contains all of the information about those items. For `Get-Process`, that table consists of something like 67 columns, with one row for

each process that's running on your computer. Each column contains a bit of information, such as virtual memory, CPU utilization, process name, process ID, and so on. Then, PowerShell looks to see whether you've specified which of those columns you want to view. If you haven't (and we haven't shown you how yet), the shell looks up a configuration file provided by Microsoft and displays only those table columns that Microsoft thinks you want to see.

One way to see all of the columns is to use `ConvertTo-HTML`:

```
Get-Process | ConvertTo-HTML | Out-File processes.html
```

That cmdlet doesn't bother filtering the columns. Instead, it produces an HTML file that contains all of them. That's one way to see the entire table.

In addition to all of those columns of information, each table row has actions associated with it. Those actions include what the operating system can do to, or with, the process listed in that table row. For example, the operating system can close a process, kill it, refresh its information, or wait for the process to exit, among other things.

Anytime you run a command that produces output, that output takes the form of a table in memory. When you pipe output from one command to another, like this

```
Get-Process | ConvertTo-HTML
```

the entire table is passed through the pipeline. The table isn't filtered down to a smaller number of columns until every command has run.

Now for some terminology changes. PowerShell doesn't refer to this in-memory table as a *table*. Instead, it uses these terms:

- *Object*—This is what we've been calling a *table row*. It represents a single thing, such as a single process or a single service.
- *Property*—This is what we called a *table column*. It represents one piece of information about an object, such as a process name, process ID, or service status.
- *Method*—This is what we called an *action*. A method is related to a single object and makes that object do something—for example, killing a process or starting a service.
- *Collection*—This is the entire set of objects, or what we've been calling a *table*.

If you find the following discussion on objects to be confusing, refer to this four-point list. Always imagine a *collection* of objects as being a big, in-memory table of information, with *properties* as the columns and individual *objects* as the rows.

8.2 ***Understanding why PowerShell uses objects***

One of the reasons that PowerShell uses objects to represent data is that, well, you have to represent data *somewhat*, right? PowerShell could have stored that data in a format such as XML, or perhaps its creators could have decided to use plain-text tables. But they had specific reasons for not taking that route.

The first reason is that Windows itself is an object-oriented operating system—or at least, most of the software that runs on Windows is object oriented. Choosing to structure data as a set of objects is easy, because most of the operating system lends itself to those structures.

Another reason to use objects is that they ultimately make things easier on you and give you more power and flexibility. For the moment, let's pretend that PowerShell doesn't produce objects as the output of its commands. Instead, it produces simple text tables, which is what you probably thought it was doing in the first place. When you run a command such as `Get-Process`, you're getting formatted text as the output:

```
PS C:\> get-process
```

Handles	NPM (K)	PM (K)	WS (K)	VM (M)	CPU (s)	Id	ProcessName
39	5	1876	4340	52	11.33	1920	conhost
31	4	792	2260	22	0.00	2460	conhost
29	4	828	2284	41	0.25	3192	conhost
574	12	1864	3896	43	1.30	316	csrss
181	13	5892	6348	59	9.14	356	csrss
306	29	13936	18312	139	4.36	1300	dfssrs
125	15	2528	6048	37	0.17	1756	dfssvc
5159	7329	85052	86436	118	1.80	1356	dns

What if you want to do something else with this information? Perhaps you want to make a change to all of the processes running Conhost. To do this, you have to filter the list a bit. In a UNIX or Linux shell, you use a command such as `grep`, telling it, “Look at this text list for me. Keep only those rows where columns 58–64 contain the characters `conhost`. Delete all of the other rows.” The resulting list contains only those processes you specified:

Handles	NPM (K)	PM (K)	WS (K)	VM (M)	CPU (s)	Id	ProcessName
39	5	1876	4340	52	11.33	1920	conhost
31	4	792	2260	22	0.00	2460	conhost
29	4	828	2284	41	0.25	3192	conhost

You then pipe that text to another command, perhaps telling it to extract the process ID from the list. “Go through this and get the characters from columns 52–56, but drop the first two (header) rows.” The result might be this:

```
1920
2460
3192
```

Finally, you pipe *that* text to yet *another* command, asking it to kill the processes (or whatever else you were trying to do) represented by those ID numbers.

This is exactly how UNIX and Linux administrators work. They spend a lot of time learning how to get better at parsing text, using tools such as `grep`, `awk`, and `sed`, and becoming proficient in the use of regular expressions. Going through this learning

process makes it easier for them to define the text patterns they want their computer to look for. UNIX and Linux folks like programming languages such as Perl because those languages contain rich text-parsing and text-manipulation functions.

But this text-based approach does present some problems:

- You can spend more time messing around with text than doing your real job.
- If the output of a command changes—say, moving the `ProcessName` column to the start of the table—then you have to rewrite all of your commands, because they’re all dependent on things like column positions.
- You have to become proficient in languages and tools that parse text—not because your job involves parsing text, but because parsing text is a means to an end.

PowerShell’s use of objects helps to remove all of that text-manipulation overhead. Because objects work like tables in memory, you don’t have to tell PowerShell which text column a piece of information is located at. Instead, you tell it the column name, and PowerShell knows exactly where to go to get that data. Regardless of how you arrange the final output on the screen or in a file, the in-memory table is always the same, so you never have to rewrite your commands because a column moved. You spend a lot less time on overhead tasks, and more time focusing on what you want to accomplish.

True, you do have to learn a few syntax elements that let you properly instruct PowerShell, but you have to learn a *lot* less than if you were working in a purely text-based shell on Windows.

DON’T GET MAD None of the preceding is intended as a dig at Linux or UNIX, by the way. They’re text-based operating systems, so working with text makes a lot of sense for them. Windows isn’t text-based, though. It’s an API-based operating system that relies heavily on object models. So PowerShell is working with Windows in a more native fashion.

8.3 **Discovering objects: Get-Member**

If objects are like a giant table in memory, and PowerShell shows you only a portion of that table on the screen, how can you see what else you have to work with? If you’re thinking that you should use the `Help` command, we’re glad, because we’ve certainly been pushing that down your throat in the previous few chapters. But unfortunately, you’d be wrong.

The help system documents only background concepts (in the form of the `about` help topics) and command syntax. To learn more about an object, you use a different command: `Get-Member`. You should become comfortable using this command—so much so, that you start looking for a shorter way to type it. We’ll give you that right now: the alias `Gm`.

You can use `Gm` after any cmdlet that normally produces output. For example, you already know that running `Get-Process` produces output on the screen. You can pipe it to `Gm`:

```
Get-Process | Gm
```

Whenever a cmdlet produces a collection of objects, as `Get-Process` does, the entire collection remains accessible until the end of the pipeline. It's not until every command has run that PowerShell filters the columns of information to be displayed and creates the final text output you see. Therefore, in the preceding example, `Gm` has complete access to all of the process objects' properties and methods, because they haven't been filtered for display yet. `Gm` looks at each object and constructs a list of the objects' properties and methods. It looks like this:

```
PS C:\> get-process | gm

TypeName: System.Diagnostics.Process
Name          MemberType      Definition
----          -----          -----
Handles       AliasProperty  Handles = HandleCount
Name          AliasProperty  Name = ProcessName
NPM           AliasProperty  NPM = NonPagedSystemMemorySize
PM            AliasProperty  PM = PagedMemorySize
VM            AliasProperty  VM = VirtualMemorySize
WS            AliasProperty  WS = WorkingSet
Disposed      Event          System.EventHandler Disposed...
ErrorDataReceived Event        System.Diagnostics.DataReader
Exited        Event          System.EventHandler Exited...
OutputDataReceived Event        System.Diagnostics.DataReader
BeginErrorReadLine Method      System.Void BeginErrorReadLine...
BeginOutputReadLine Method      System.Void BeginOutputReadLine...
CancelErrorRead  Method      System.Void CancelErrorRead...
CancelOutputRead Method      System.Void CancelOutputRead...
```

We've trimmed the preceding list because it's long, but hopefully you get the idea.

TRY IT NOW Don't take our word for it. This is the perfect time to follow along and run the same commands we do, to see their complete output.

By the way, it may interest you to know that all of the properties, methods, and other things attached to an object are collectively called its *members*, as if the object itself were a country club and all of these properties and methods belonged to the club. That's where `Get-Member` takes its name from: It's getting a list of the objects' members. But remember, because the PowerShell convention is to use singular nouns, the cmdlet name is `Get-Member`, not `Get-Members`.

IMPORTANT It's easy to overlook, but pay attention to the first line of output from `Get-Member`. It's `TypeName`, which is the unique name assigned to that particular type of object. It may seem unimportant now—after all, who cares what it's named? But it's going to become crucial in the next chapter.

8.4 Using object attributes, or properties

When you examine the output of `Get-Member`, you'll notice several kinds of properties:

- `ScriptProperty`
- `Property`
- `NoteProperty`
- `AliasProperty`

Above and beyond

Normally, objects in the .NET Framework—which is where all of PowerShell's objects come from—have only *properties*. PowerShell dynamically adds the other stuff: `ScriptProperty`, `NoteProperty`, `AliasProperty`, and so on. If you happen to look up an object type in Microsoft's MSDN documentation (you can plug the object's `TypeName` into your favorite search engine to find the MSDN page), you won't see these extra properties.

PowerShell has an Extensible Type System (ETS) that's responsible for adding these last-minute properties. Why does it do this? In some cases, it's to make objects more consistent, such as adding a `Name` property to objects that natively have only something like `ProcessName` (that's what an `AliasProperty` is for). Sometimes it's to expose information that's deeply buried in the object (process objects have a few `ScriptProperties` that do this).

Once you're in PowerShell, these properties all behave the same way. But don't be surprised when they don't show up on the official documentation page: The shell adds these extras, often to make your life easier.

For your purposes, these properties are all the same. The only difference is in how the properties were originally created, but that's not something you need to worry about. To you, they're all properties, and you'll use them the same way.

A property always contains a value. For example, the value of a process object's `ID` property might be `1234`, and the `Name` property of that object might have a value of `Notepad`. Properties describe something about the object: its status, its ID, its name, and so on. In PowerShell, properties are often read-only, meaning you can't change the name of a service by assigning a new value to its `Name` property. But you can retrieve the name of a service by reading its `Name` property. We estimate that 90% of what you'll do in PowerShell will involve properties.

8.5 Using object actions, or methods

Many objects support one or more methods, which, as we mentioned earlier, are actions that you can direct the object to take. A process object has a `Kill` method, which terminates the process. Some methods require one or more input arguments that provide additional details for that particular action, but you won't be running into any of those this early in your PowerShell education. You may spend months or

even years working with PowerShell and never need to execute a single object method. That's because many of those actions are also provided by cmdlets.

For example, if you need to terminate a process, you have three ways to do so. One way is to retrieve the object and then somehow execute its `Kill` method. Another way is to use a couple of cmdlets:

```
Get-Process -Name Notepad | Stop-Process
```

You can also accomplish that by using a single cmdlet:

```
Stop-Process -name Notepad
```

Our focus in this book is entirely on using PowerShell cmdlets to accomplish tasks. They provide the easiest, most administrator-centric, most task-focused way of accomplishing things. Using methods starts to edge into .NET Framework programming, which can be more complicated and can require a lot more background information. For that reason, you'll rarely—if ever—see us execute an object method in this book. Our general philosophy at this point is, “If you can't do it with a cmdlet, go back and use the GUI.” You won't feel that way for your entire career, we promise, but for now it's a good way to stay focused on the “PowerShell way” of doing things.

Above and beyond

You don't need to know about them at this stage in your PowerShell education, but in addition to properties and methods, objects can also have events. An event is an object's way of notifying you that something happened to it. A process object, for example, can trigger its `Exited` event when the process ends. You can attach your own commands to those events, so that, for example, an email is sent when a process exits. Working with events in this fashion is an advanced topic that's beyond the scope of this book.

8.6 **Sorting objects**

Most PowerShell cmdlets produce objects in a deterministic fashion, which means that they tend to produce objects in the same order every time you run the command. Both services and processes, for example, are listed in alphabetical order by name. Event log entries tend to come out in chronological order. What if we want to change that?

For example, suppose we want to display a list of processes, with the biggest consumers of virtual memory (VM) at the top of the list, and the smallest consumers at the bottom. We need to somehow reorder that list of objects based on the `VM` property. PowerShell provides a simple cmdlet, `Sort-Object`, which does exactly that:

```
Get-Process | Sort-Object -property VM
```

TRY IT NOW We're hoping that you'll follow along and run these same commands. We aren't pasting the output into the book because these tables are long, but you'll get approximately the same thing on your screen if you're following along.

That command isn't exactly what we want. It does sort on VM, but it does so in ascending order, with the largest values at the bottom of the list. Reading the help for Sort-Object, we see that it has a -descending parameter that should reverse the sort order. We also notice that the -property parameter is positional, so we don't need to type the parameter name. We'll also tell you that Sort-Object has an alias, Sort, so you can save yourself a bit of typing for the next try:

```
Get-Process | Sort VM -desc
```

We abbreviated -descending to -desc, and we have the result we want. The -property parameter accepts multiple values (which we're sure you saw in the help file, if you looked).

In the event that two processes are using the same amount of virtual memory, we want them sorted by process ID, and the following command accomplishes that:

```
Get-Process | Sort VM, ID -desc
```

As always, a comma-separated list is the way to pass multiple values to any parameter that supports them.

8.7 Selecting the properties you want

Another useful cmdlet is Select-Object. It accepts objects from the pipeline, and you can specify the properties that you want displayed. This enables you to access properties that are normally filtered out by PowerShell's configuration rules, or to trim down the list to a few properties that interest you. This can be useful when piping objects to ConvertTo-HTML, because that cmdlet usually builds a table containing every property.

Compare the results of these two commands:

```
Get-Process | ConvertTo-HTML | Out-File test1.html  
Get-Process | Select-Object -property Name, ID, VM, PM |  
ConvertTo-HTML | Out-File test2.html
```

TRY IT NOW Go ahead and run each of these commands separately, and then examine the resulting HTML files in Internet Explorer to see the differences.

Take a look at the help for Select-Object (or you can use its alias, Select). The -property parameter appears to be positional, which means we could shorten that last command:

```
Get-Process | Select Name, ID, VM, PM | ConvertTo-HTML | Out-File test3.html
```

Spend some time experimenting with Select-Object. Try variations of the following command, which allows the output to appear on the screen:

```
Get-Process | Select Name, ID, VM, PM
```

Try adding and removing different process object properties from that list and reviewing the results. How many properties can you specify and still get a table as the output? How many properties force PowerShell to format the output as a list rather than as a table?

Above and beyond

Select-Object also has `-First` and `-Last` parameters, which let you keep a subset of the objects in the pipeline. For example, `Get-Process | Select -First 10` keeps the first 10 objects. There are no criteria involved, such as keeping certain processes; it's merely grabbing the first (or last) 10.

CAUTION People often get mixed up about two PowerShell commands: `Select-Object` and `Where-Object`, which you haven't seen yet. `Select-Object` is used to choose the properties (or columns) you want to see, and it can also select an arbitrary subset of output rows (using `-First` and `-Last`). `Where-Object` removes, or filters, objects out of the pipeline based on criteria you specify.

8.8 Objects until the end

The PowerShell pipeline always contains objects until the last command has been executed. At that time, PowerShell looks to see what objects are in the pipeline, and then looks at its various configuration files to see which properties to use to construct the onscreen display. It also decides whether that display will be a table or a list, based on internal rules and on its configuration files. (We'll explain more about those rules and configurations, and how you can modify them, in chapter 10.)

An important fact is that the pipeline can contain many kinds of objects over the course of a single command line. For the next few examples, we're going to take a single command line and physically type it so that only one command appears on a single line of text. That'll make it a bit easier to explain what we're talking about.

Here's the first one:

```
Get-Process |
Sort-Object VM -descending |
Out-File c:\procs.txt
```

In this example, we start by running `Get-Process`, which puts process objects into the pipeline. The next command is `Sort-Object`. That doesn't change what's in the pipeline; it changes only the order of the objects, so at the end of `Sort-Object`, the pipeline still contains processes. The last command is `Out-File`. Here, PowerShell has to produce output, so it takes whatever's in the pipeline—processes—and formats them according to its internal rule set. The results go into the specified file.

Next up is a more complicated example:

```
Get-Process |
Sort-Object VM -descending |
Select-Object Name, ID, VM
```

This starts off in the same way. `Get-Process` puts process objects into the pipeline. Those go to `Sort-Object`, which sorts them and puts the same process objects into the pipeline. But `Select-Object` works a bit differently. A process object always has the exact same members. In order to trim down the list of properties, `Select-Object` can't remove the properties you don't want, because the result wouldn't be a process object anymore. Instead, `Select-Object` creates a new kind of custom object called a `PSObject`. It copies over the properties you do want from the process, resulting in a custom object being placed into the pipeline.

TRY IT NOW Try running this three-cmdlet command line, keeping in mind that you should type the whole thing on a single line. Notice how the output is different from the normal output of `Get-Process`?

When PowerShell sees that it's reached the end of the command line, it has to decide how to lay out the text output. Because there are no longer any process objects in the pipeline, PowerShell won't use the default rules and configurations that apply to process objects. Instead, it looks for rules and configurations for a `PSObject`, which is what the pipeline now contains. Microsoft doesn't provide any rules or configurations for `PSObjects`, because they're meant to be used for custom output. Instead, PowerShell takes its best guess and produces a table, on the theory that those three pieces of information probably will still fit in a table. The table isn't as nicely laid out as the normal output of `Get-Process`, though, because the shell lacks the additional configuration information needed to make a nicer-looking table.

You can use `gm` to see the objects that wind up in the pipeline. Remember, you can add `gm` after any cmdlet that produces output:

```
Get-Process | Sort VM -descending | gm
Get-Process | Sort VM -descending | Select Name, ID, VM | gm
```

TRY IT NOW Try running those two command lines separately, and notice the difference in the output.

Notice that, as part of the `gm` output, PowerShell shows you the type name for the object it sees in the pipeline. In the first case, that's a `System.Diagnostics.Process` object, but in the second case the pipeline contains a different kind of object. Those new *selected* objects contain only the three properties specified—`Name`, `ID`, and `VM`—plus a couple of system-generated members.

Even `gm` produces objects and places them into the pipeline. After running `gm`, the pipeline no longer contains either process or the *selected* objects; it contains the type of

object produced by `Gm`: a `Microsoft.PowerShell.Commands.MemberDefinition`. You can prove that by piping the output of `Gm` to `Gm` itself:

```
Get-Process | Gm | Gm
```

TRY IT NOW You'll definitely want to try this, and think hard about it to make sure it makes sense to you. You start with `Get-Process`, which puts process objects into the pipeline. Those go to `Gm`, which analyzes them and produces its own `MemberDefinition` objects. Those are then piped to `Gm`, which analyzes them and produces output that lists the members of each `MemberDefinition` object.

A key to mastering PowerShell is learning to keep track of the kind of object that's in the pipeline at any given point. `Gm` can help you do that, but sitting back and verbally walking yourself through the command line is also a good exercise that can help clear up confusion.

8.9 Common points of confusion

Our classroom students tend to make a few common mistakes as they get started with PowerShell. Most of these go away with a little experience, but we direct your attention to them with the following list, to give you a chance to catch yourself if you start heading down the wrong path.

- Remember that the PowerShell help files don't contain information on objects' properties. You'll need to pipe the objects to `Gm` (`Get-Member`) to see a list of properties.
- Remember that you can add `Gm` to the end of any pipeline that typically produces results. A command line such as `Get-Process -name Notepad | Stop-Process` doesn't usually produce results, so tacking `| Gm` onto the end won't produce anything either.
- Pay attention to neat typing. Put a space on either side of every pipeline character, because your command lines should read as `Get-Process | Gm` and not `Get-Process|Gm`. That spacebar key is extra large for a reason—use it.
- Remember that the pipeline can contain various types of objects at each step. Think about what type of object is in the pipeline, and focus on what the next command will do to that *type* of object.

8.10 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

This chapter has probably covered more, and more difficult, new concepts than any chapter to this point. We hope that you were able to make sense of it all and that these exercises will help you cement what you've learned. Some of these tasks draw on skills you've learned in previous chapters, to refresh your memory and keep you sharp.

- 1 Identify a cmdlet that produces a random number.
- 2 Identify a cmdlet that displays the current date and time.
- 3 What type of object does the cmdlet from task 2 produce? (What is the *type name* of the object produced by the cmdlet?)
- 4 Using the cmdlet from task 2 and `Select-Object`, display only the current day of the week in a table like the following (Caution: the output will right-align, so make sure your PowerShell window doesn't have a horizontal scrollbar):

```
DayOfWeek
-----
Monday
```
- 5 Identify a cmdlet that displays information about installed hotfixes on Windows systems.
- 6 Using the cmdlet from task 5, display a list of installed hotfixes. Then extend the expression to sort the list by the installation date, and display only the installation date, the user who installed the hotfix, and the hotfix ID. Remember that the column headers shown in a command's default output aren't necessarily the real property names—you need to look up the real property names to be sure.
- 7 Repeat task 6, but this time sort the results by the hotfix description, and include the description, the hotfix ID, and the installation date. Put the results into an HTML file.
- 8 Display a list of the 50 newest entries from the Security event log (you can use a different log, such as System or Application, if your Security log is empty). Sort the list with the oldest entries appearing first, and with entries made at the same time sorted by their index. Display the index, time, and source for each entry. Put this information into a text file (not an HTML file, but a plain-text file). You may be tempted to use `Select-Object` and its `-first` or `-last` parameters to achieve this; don't. There's a better way. Also, avoid using `Get-WinEvent` for now; a better cmdlet is available for this particular task.

8.11 Lab answers

- 1 `Get-Random`
- 2 `Get-Date`
- 3 `System.DateTime`
- 4 `Get-Date | select DayofWeek`
- 5 `Get-Hotfix`
- 6 `Get-HotFix | Sort InstalledOn | Select InstalledOn, InstalledBy, HotFixID`
- 7 `Get-HotFix | Sort Description | Select Description, InstalledOn, InstalledBy, HotFixID | ConvertTo-HTML -Title "HotFix Report" | Out-File HotFixReport.htm`
- 8 `Get-EventLog -LogName System -Newest 50 | Sort TimeGenerated, Index | Select Index, TimeGenerated, Source | Out-File elogs.txt`

The pipeline, deeper

At this point, you've learned to be pretty effective with PowerShell's pipeline. Running commands (for example, `Get-Process | Sort VM -desc | ConvertTo-HTML | Out-File procs.html`) is powerful, accomplishing in one line what used to take several lines of script. But you can do even better. In this chapter, we dig deeper into the pipeline and uncover some of its most powerful capabilities.

9.1 *The pipeline: enabling power with less typing*

One of the reasons we like PowerShell so much is that it enables us to be more effective administrators without having to write complex scripts, as we used to have to do in VBScript. But the key to powerful one-line commands lies in the way the PowerShell pipeline works.

Let us be clear: You could skip this chapter and still be effective with PowerShell, but you'd in most cases have to resort to VBScript-style scripts and programs. Although PowerShell's pipeline capabilities can be complicated, they're probably easier to learn than more-complicated programming skills. By learning to manipulate the pipeline, you can be much more effective without needing to write scripts.

The whole idea here is to get the shell to do more of your work for you, with as little typing as possible. We think you'll be surprised at how well the shell can do that!

9.2 *How PowerShell passes data down the pipeline*

Whenever you string together two commands, PowerShell has to figure out how to get the output of the first command to the input of the second command. In the upcoming examples, we refer to the first command as *Command A*. That's the

command that produces something. The second command is *Command B*, which needs to accept Command A's output and then do its own thing.

```
PS C:\> CommandA | CommandB
```

For example, suppose you have a text file that contains one computer name on each line, as shown in figure 9.1.

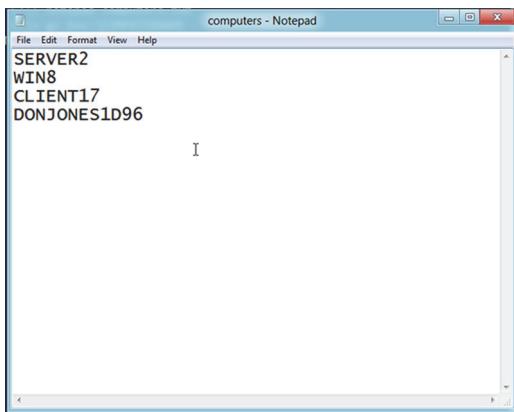

Figure 9.1 Creating a text file containing computer names, with one name per line

You might want to use those computer names as the input to a command, telling that command which computers you want it to run against. Consider this example:

```
PS C:\> Get-Content .\computers.txt | Get-Service
```

When `Get-Content` runs, it places the computer names into the pipeline. PowerShell then has to decide how to get those to the `Get-Service` command. The trick with PowerShell is that commands can accept input only on a parameter. PowerShell has to figure out which parameter of `Get-Service` will accept the output of `Get-Content`. This figuring-out process is called *pipeline parameter binding*, and it's what we cover in this chapter. PowerShell has two methods for getting the output of `Get-Content` onto a parameter of `Get-Service`. The first method the shell will try is called `ByValue`; if that doesn't work, it'll try `ByPropertyName`.

9.3 Plan A: pipeline input `ByValue`

With this method of pipeline parameter binding, PowerShell looks at the type of object produced by Command A and tries to see whether any parameter of Command B can accept that type of object from the pipeline. You can determine this for yourself: First pipe the output of Command A to `Get-Member`, to see what type of object Command A is producing. Then examine the full help of Command B (for example, `Help Get-Service -full`) to see whether any parameter accepts that type of data from the pipeline `ByValue`. Figure 9.2 shows what you might discover.

What you'll find is that `Get-Content` produces objects of the type `System.String` (or `String` for short). You'll also find that `Get-Service` does have a parameter that

The screenshot shows two side-by-side Windows PowerShell windows. The left window shows the output of the command `Get-Content .\computers.txt | Get-Member`. It lists numerous methods for the `String` type, including `Clone`, `CompareTo`, `Contains`, `CopyTo`, `EndsWith`, `Equals`, `GetEnumerator`, `GetHashCode`, `GetType`, `GetTypeCode`, `IndexOf`, `IndexOfAny`, `Insert`, `IsNormalized`, `LastIndexOf`, `LastIndexOfAny`, `Normalize`, `PadLeft`, `PadRight`, `Remove`, `Replace`, `Split`, and `StartsWith`. The `TypeName: System.String` line is highlighted with a red box. An arrow points from this box to the `-Name <String[]>` parameter in the right window.

The right window shows the help documentation for the `Get-Service` cmdlet. It details the parameters for retrieving service controllers. The `-Name <String[]>` parameter is described as specifying service names, with its help text also enclosed in a red box. Another arrow points from the `-Name` parameter in the right window back to the `TypeName: System.String` line in the left window.

Figure 9.2 Comparing the output of `Get-Content` to the input parameters of `Get-Service`

accepts `String` from the pipeline `ByValue`. The problem is that it's the `-Name` parameter, which according to the help “specifies the service names of services to be retrieved.” That isn't what we want—our text file, and therefore our `String` objects, are computer names, not service names. If we ran the following

```
PS C:\> Get-Content .\computers.txt | Get-Service
```

we'd be attempting to retrieve services named SERVER2, WIN8, and so forth, which is probably not going to work.

PowerShell permits only one parameter to accept a given type of object from the pipeline `ByValue`. Because the `-Name` parameter accepts `String` from the pipeline `ByValue`, no other parameter can do so. That dashes our hopes for trying to pipe computer names from our text file to `Get-Service`.

In this case, pipeline input is working, but it isn't achieving the results we're hoping for. Let's consider a different example, where we do get the results we want. Here's the command line:

```
PS C:\> get-process -name note* | Stop-Process
```

Administrator: Windows PowerShell

```
PS C:\> get-process -name * |
>> get-member
>>

TypeName: System.Diagnostics.Process
```

  Default value
  Accept pipeline input? true (ByPropertyName)
  Accept wildcard characters? true

-PassThru [<SwitchParameter>]
  Returns an object representing the process. By default, this
```

Figure 9.3 Binding the output of Get-Process to a parameter of Stop-Process

Let's pipe the output of Command A to Get-Member and examine the full help for Command B. Figure 9.3 shows what you'll find.

Get-Process produces objects of the type `System.Diagnostics.Process` (note that we limit the command to processes whose names start with note*; we also make sure a copy of Notepad is running so that the command produces output). Stop-Process can accept those Process objects from the pipeline `ByValue`; it does so on its `-InputObject` parameter. According to the help, that parameter "stops the processes represented by the specified process objects." In other words, Command A gets one or more Process objects, and Command B stops (or kills) them.

This is a good example of pipeline parameter binding in action, and it also illustrates an important point in PowerShell: For the most part, commands sharing the same noun (as Get-Process and Stop-Process do) can usually pipe to each other `ByValue`.

The screenshot shows two adjacent Windows PowerShell windows. The left window, titled 'Administrator: Windows PowerShell', displays the command 'Get-Service -name s* |' followed by a list of service objects. One object, 'ServiceController', is highlighted with a red box. The right window, also titled 'Administrator: Windows PowerShell', shows the help documentation for the 'Stop-Process' cmdlet. The 'NAME' section lists 'Stop-Process'. The 'SYNOPSIS' section describes stopping one or more running processes. The 'SYNTAX' section shows examples of the cmdlet's usage. The 'DESCRIPTION' section provides details about stopping processes, mentioning that it works only on processes running on the local computer and requires 'Run as administrator' on Vista and later versions. A cursor is visible in the right window's scroll bar.

```

Administrator: Windows PowerShell

NAME
Stop-Process

SYNOPSIS
Stops one or more running processes.

SYNTAX

```

Stop-Process [-Id] <Int32[]> [-Force [<SwitchParameter>]] [-PassThru [<SwitchParameter>]] [-Confirm [<SwitchParameter>]] [-WhatIf [<SwitchParameter>]] [<CommonParameters>]
Stop-Process [-InputObject] <Process[]> [-Force [<SwitchParameter>]] [-PassThru [<SwitchParameter>]] [-Confirm [<SwitchParameter>]] [-WhatIf [<SwitchParameter>]] [<CommonParameters>]
Stop-Process [-Force [<SwitchParameter>]] [-PassThru [<SwitchParameter>]] -Name <String[]> [-Confirm [<SwitchParameter>]] [-WhatIf [<SwitchParameter>]] [<CommonParameters>]

```

DESCRIPTION

The Stop-Process cmdlet stops one or more running processes. You specify a process by process name or process ID (PID), or pass a process object to Stop-Process. Stop-Process works only on processes running on the local computer.

On Windows Vista and later versions of Windows, to stop a process that is not owned by the current user, you must start Windows PowerShell with the "Run as administrator" option. Also, you are prompted for confirmation unless you use the Force parameter.

Figure 9.4 Examining the output of `Get-Service` and the input parameters of `Stop-Process`

Let's cover one more example:

```
PS C:\> get-service -name s* | stop-process
```

On the face of it, this might not seem to make any sense. But let's see this through by piping Command A's output to `Get-Member`, and reexamining the help for Command B. Figure 9.4 shows what you should find.

`Get-Service` produces objects of the type `ServiceController` (technically, `System.ServiceProcess.ServiceController`, but you can usually take the last bit of the `TypeNames` as a shortcut). Unfortunately, there isn't a single parameter of `Stop-Process` that can accept a `ServiceController` object. The `ByValue` approach has failed, and PowerShell will try its backup plan: `ByPropertyName`.

The screenshot shows two adjacent Windows PowerShell windows. The left window displays the command:

```
PS C:\> get-service -name s* |  
>> get-member -MemberType Property, Alias  
>>
```

This command retrieves services starting with 's' and then pipes their members to the `get-member` cmdlet, filtering for properties and aliases. The output is a table:

Name	MemberType	Definition
Name	AliasProperty	Name
RequiredServices	AliasProperty	Requi
CanPauseAndContinue	Property	bool
CanShutdown	Property	bool
CanStop	Property	bool
Container	Property	Syste
DependentServices	Property	Syste
DisplayName	Property	strin
MachineName	Property	strin
ServiceHandle	Property	Syste
ServiceName	Property	strin
ServicesDependedOn	Property	Syste
ServiceType	Property	Syste
Site	Property	Syste
Status	Property	Syste

The right window shows the help documentation for the `Stop-Process` cmdlet:

```
NAME  
Stop-Process  
  
SYNOPSIS  
Stops one or more running processes.  
  
SYNTAX  
Stop-Process [-Id] <Int32[]> [-Force [<SwitchParameter>]] [-PassThru [<SwitchParameter>]] [-Confirm [<SwitchParameter>]] [-WhatIf [<SwitchParameter>]] [<CommonParameters>]  
Stop-Process [-InputObject] <Process[]> [-Force [<SwitchParameter>]] [-PassThru [<SwitchParameter>]] [-Confirm [<SwitchParameter>]] [-WhatIf [<SwitchParameter>]] [<CommonParameters>]  
Stop-Process [-Force [<SwitchParameter>]] [-PassThru [<SwitchParameter>]] -Name <String[]> [-Confirm [<SwitchParameter>]] [-WhatIf [<SwitchParameter>]] [<CommonParameters>]  
  
DESCRIPTION  
The Stop-Process cmdlet stops one or more running processes. You specify a process by process name or process ID (PID), or pass a process object to Stop-Process. Stop-Process works only on processes running on the local computer.  
  
On Windows Vista and later versions of Windows, to stop a process that is not owned by the current user, you must start Windows PowerShell with the "Run as administrator" option. Also, you are prompted for confirmation unless you use the Force parameter.
```

A red arrow points from the `Name` column in the table to the `-Name` parameter in the SYNTAX section of the help text. Another red arrow points from the `RequiredServices` column in the table to the `-PassThru` parameter in the SYNTAX section of the help text.

Figure 9.5 Mapping properties to parameters

9.4 Plan B: pipeline input ByPropertyName

With this approach, you're still looking to attach the output of Command A to parameters of Command B. But `ByPropertyName` is slightly different from `ByValue`. With this backup method, it's possible for multiple parameters of Command B to become involved. Once again, pipe the output of Command A to `Get-Member`, and then look at the syntax for Command B. Figure 9.5 shows what you should find: The output of Command A has one property whose name corresponds to a parameter on Command B.

A lot of folks overthink what's happening here, so let's be clear on how simple the shell is being: It's looking for property names that match parameter names. That's it. Because the property `Name` is spelled the same as the parameter `-Name`, the shell tries to connect the two.

```

Administrator: Windows PowerShell
PS C:\> get-service -name s* | 
>> get-member -MemberType Property, Alias
>>

TypeName: System.ServiceProcess.Service
Name          MemberType   Definition
----          --          --
Name          AliasProperty  Name

```

expression that gets the objects.

Required?	true
Position?	1
Default value	
Accept pipeline input?	true (ByValue)
Accept wildcard characters?	false

-Name <String[]>

Specifies the process names of the processes to be stopped. You can type multiple process names (separated by commas) or use wildcard characters.

Required?	true
Position?	named
Default value	
Accept pipeline input?	true (ByPropertyName)
Accept wildcard characters?	true

-PassThru [<SwitchParameter>]

Returns an object representing the process. By default, this cmdlet does not generate any output.

Required?	false
Position?	named
Default value	False
Accept pipeline input?	false
Accept wildcard characters?	false

-Confirm [<SwitchParameter>]

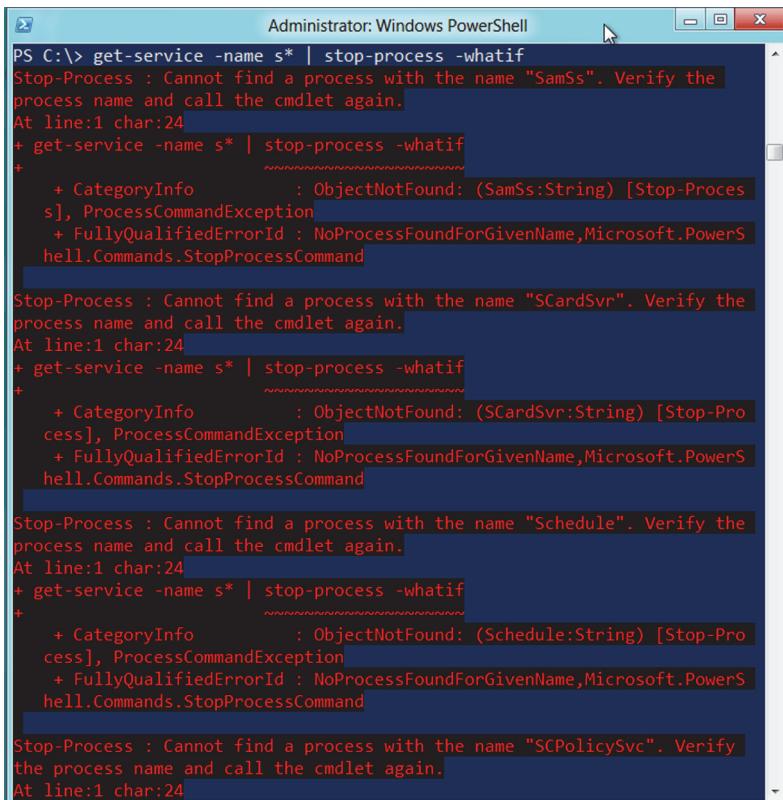

Prompts you for confirmation before running the cmdlet.

-- More --

Figure 9.6 Checking to see whether the `Stop-Process` object's `-Name` parameter accepts pipeline input `ByPropertyName`

But it can't do so right away; first it needs to see whether the `-Name` parameter will accept input from the pipeline `ByPropertyName`. A glance at the full help, shown in figure 9.6, is required to make this determination.

In this case, `-Name` does accept pipeline input `ByPropertyName`, so this connection works. Now, here's the trick: Unlike `ByValue`, which involves only one parameter, `ByPropertyName` connects every matching property and parameter (provided each parameter has been designed to accept pipeline input `ByPropertyName`). In our current example, only `Name` and `-Name` match. The results? Examine figure 9.7.

```

```

Figure 9.7 Attempting to pipe `Get-Service` to `Stop-Process`

We see a bunch of error messages. The problem is that services' names are usually things like `ShellHWDetection` and `SessionEnv`, whereas the services' executables might be things like `svchost.exe`. `Stop-Process` deals only with those executable names. But even though the `Name` property connects to the `-Name` parameter via the pipeline, the values inside the `Name` property don't make sense to the `-Name` parameter, which leads to the errors.

Let's look at a more successful example. Create a simple comma-separated values (CSV) file in Notepad, using the example in figure 9.8.

Save the file as `Aliases.csv`. Now, back in the shell, try importing it, as shown in figure 9.9. You should also pipe the output of `Import-CSV` to `Get-Member`, so that you can examine the output's members.

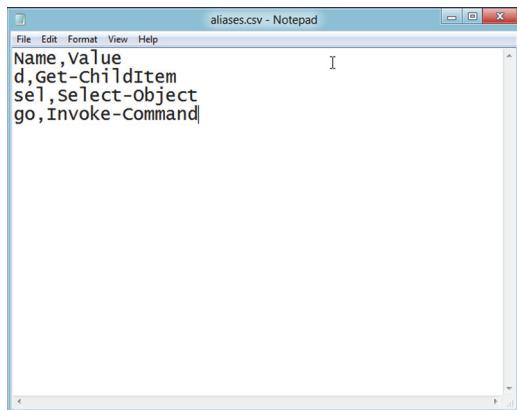

Figure 9.8 Create this CSV file in Windows Notepad.

A screenshot of an Administrator Windows PowerShell window. The title bar says "Administrator: Windows PowerShell". The command PS C:\> import-csv .\aliases.csv is run, followed by PS C:\> import-csv .\aliases.csv | get-member. The output shows the CSV data and the members of the resulting PSCustomObject:

Name	Value
d	Get-ChildItem
sel	Select-Object
go	Invoke-Command

Name	MemberType	Definition
Equals	Method	bool Equals(System.Object obj)
GetHashCode	Method	int GetHashCode()
GetType	Method	type GetType()
ToString	Method	string ToString()
Name	NoteProperty	System.String Name=d
Value	NoteProperty	System.String Value=Get-ChildItem

Figure 9.9 Importing the CSV file and checking its members

The screenshot shows two adjacent Windows PowerShell windows. The left window, titled 'Administrator: Window', displays the command PS C:\> import-csv .\aliases.csv followed by its output, which is a table of properties and their values:

Name	Value
d	Get-ChildItem
sel	Select-Object
go	Invoke-Command

The right window, also titled 'Administrator: Windows PowerShell', shows the help for the New-Alias cmdlet. Red arrows point from the 'Name' and 'Value' columns in the CSV output to the corresponding parameter descriptions in the cmdlet's help documentation.

```

NAME
  New-Alias
  ...
SYNOPSIS
  Creates a new alias.
...
SYNTAX
  New-Alias [-Name] <String> [-Value] <String> [-Description <String>]
  [-Force [<SwitchParameter>]] [-Option <ScopedItemOptions>] [-Passthru]
  [-Scope <String>] [<CommonParameters>]
...
DESCRIPTION
  The New-Alias cmdlet creates a new alias in the current Windows PowerShell session. Aliases created by using New-Alias are not saved after you exit the session or close Windows PowerShell. You can use the Export-Alias cmdlet to save your alias information to a file so you can later use Import-Alias to retrieve that saved alias information.
...
PARAMETERS
  -Name <String>
    Specifies a name for the alias. You can type any string, but if the description includes spaces, enclose it in quotation marks.
    Required?           false
    Position?          named
    Default value
    Accept pipeline input?   false
    Accept wildcard characters? false
  ...
  -- More -- 

```

Figure 9.10 Matching properties to parameter names

You can clearly see that the columns from the CSV file become properties, and each data row in the CSV file becomes an object. Now, examine the help for New-Alias, as shown in figure 9.10.

Both properties (Name and Value) correspond to parameter names of New-Alias. Obviously, this was done on purpose—when you create the CSV file, you can name those columns anything you want. Now, check whether -Name and -Value accept pipeline input ByPropertyName, as shown in figure 9.11.

Both parameters do, meaning this trick works. Try running the command:

```
PS C:\> import-csv .\aliases.csv | new-alias
```

The result is three new aliases, named d, sel, and go, which point to the commands Get-ChildItem, Select-Object, and Invoke-Command, respectively. This is a powerful technique for passing data from one command to another, and for accomplishing complex tasks in a minimum number of commands.

The screenshot shows two adjacent Windows PowerShell windows. The left window displays the command `PS C:\> import-csv .\aliases.csv` followed by the output of the `Get-Alias` cmdlet. The right window shows the detailed help for the `Get-Alias` cmdlet, specifically focusing on the parameters and their descriptions.

```

Administrator: Windows PowerShell
PS C:\> import-csv .\aliases.csv
Name          Value
----          -----
d             Get-AdUser
sel            Set-AdUser
go             Import-Module ActiveDirectory

PS C:\> import-csv .\aliases.csv | get-alias
TypeNames: System.Management.Automation.AliasInfo

Name      MemberType   Definition
----      -----        -----
Equals    Method       bool Equals(System.Object)
GetHashCode Method       int GetHashCode()
GetType   Method       type GetType()
ToString  Method       string ToString()
Name      NoteProperty System.String
Value    NoteProperty System.String

PS C:\>

```

Right Window Content:

```

-Scope <String>
  Specifies the scope of the new alias. Valid values are "Global", "Local", or "Script", or a number relative to the current scope (0 through the number of scopes, where 0 is the current scope and 1 is its parent). "Local" is the default. For more information see about_Scopes.

  Required?           false
  Position?          named
  Default value      Local
  Accept pipeline input?  false
  Accept wildcard characters?  false

-Value <String>
  Specifies the name of the cmdlet or command element that is aliased.

  Required?           true
  Position?          2
  Default value      2
  Accept pipeline input?  true (ByPropertyName)
  Accept wildcard characters?  false

<CommonParameters>
  This cmdlet supports the common parameters: Verbose, Debug, ErrorAction, ErrorVariable, WarningAction, WarningVariable, OutBuffer and OutVariable. For more information, see about_CommonParameters
  (http://go.microsoft.com/fwlink/?LinkID=113216).

INPUTS
  None

```

Figure 9.11 Looking for parameters that accept pipeline input `ByPropertyName`

9.5 When things don't line up: custom properties

The CSV example is cool, but it's pretty easy to make property and parameter names line up when you're creating the input from scratch. Things get tougher when you're forced to deal with objects that are created for you, or data that's being produced by someone else.

For this example, we introduce a new command that you might not have access to: `New-ADUser`. It's part of the ActiveDirectory module, which you'll find on any Windows Server 2008 R2 (or later) domain controller. You can also get that module on a client computer by installing Microsoft's Remote Server Administration Tools (RSAT). But for now, don't worry about running the command; follow along with the example.

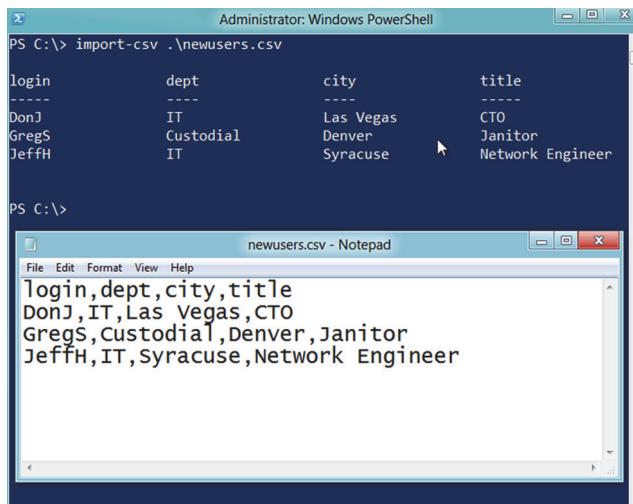

`New-ADUser` has parameters designed to accept information about a new Active Directory user. Here are some examples:

- -Name (mandatory)
- -samAccountName (technically not mandatory, but you have to provide it to make the account usable)

- -Department
- -City
- -Title

We could cover the others, but let's work with these. All of them accept pipeline input ByPropertyName.

For this example, we'll again assume you're getting a CSV file, but it's coming from your company's Human Resources or Personnel department. You've given them your desired file format a dozen times, but they persist in giving you something that's close, but not quite right, as shown in figure 9.12.

The screenshot shows two windows. The top window is 'Administrator: Windows PowerShell' with the command 'PS C:\> import-csv .\newusers.csv'. It displays a table with four columns: login, dept, city, and title. The data is as follows:

login	dept	city	title
DonJ	IT	Las Vegas	CTO
GregS	Custodial	Denver	Janitor
JeffH	IT	Syracuse	Network Engineer

The bottom window is 'newusers.csv - Notepad' showing the original CSV file content:

```
Login,dept,city,title
DonJ,IT,Las Vegas,CTO
GregS,Custodial,Denver,Janitor
JeffH,IT,Syracuse,Network Engineer
```

Figure 9.12 Working with the CSV file provided by Human Resources

As you can see in figure 9.12, the shell can import the CSV file fine, resulting in three objects with four properties apiece. The problem is that the dept property won't line up with the -Department parameter of New-ADUser, the login property is meaningless, and you don't have samAccountName or Name properties—both of which are required if you want to be able to run this command to create new users:

```
PS C:\> import-csv .\newusers.csv | new-aduser
```

How can you fix this? You could open the CSV file and fix it, but that's a lot of manual work over time, and the whole point of PowerShell is to reduce manual labor. Why not set up the shell to fix it instead? Look at the following example:

```
PS C:\> import-csv .\newusers.csv |
>> select-object -property *,
>> @{name='samAccountName';expression={$_.login}},
>> @{label='Name';expression={$_.login}},
>> @{n='Department';e={$_.Dept}}
>>
```

```

login      : DonJ
dept       : IT
city       : Las Vegas
title      : CTO
samAccountName : DonJ
Name       : DonJ
Department : IT
login      : GregS
dept       : Custodial
city       : Denver
title      : Janitor
samAccountName : GregS
Name       : GregS
Department : Custodial
login      : JeffH
dept       : IT
city       : Syracuse
title      : Network Engineer
samAccountName : JeffH
Name       : JeffH
Department : IT

```

That's some pretty funky syntax, so let's break it down:

- We use `Select-Object` and its `-Property` parameter. We start by specifying the property `*`, which means “all of the existing properties.” Notice that the `*` is followed by a comma, which means we’re continuing the list of properties.
- We then create a hash table, which is the construct starting with `@{` and ending with `}`. Hash tables consist of one or more key=value pairs, and `Select-Object` has been programmed to look for specific keys, which we’ll provide to it.
- The first key that `Select-Object` wants can be `Name`, `N`, `Label`, or `L`, and the value for that key is the name of the property we want to create. In the first hash table, we specify `samAccountName`; in the second, `Name`; and in the third, `Department`. These correspond to the parameter names of `New-ADUser`.
- The second key that `Select-Object` needs can be either `Expression` or `E`. The value for this key is a script block, contained within {curly brackets}. Within that script block, you use the special `$_` placeholder to refer to the existing piped-in object (the original row of data from the CSV file) followed by a period. `$_` lets you access one property of the piped-in object, or one column of the CSV file. This specifies the contents for the new properties.

TRY IT NOW Go ahead and create the CSV file that’s shown in figure 9.12. Then try running the exact command we did previously—you can type it exactly as shown.

What we’ve done is taken the contents of the CSV file—the output of `Import-CSV`—and modified it, dynamically, in the pipeline. Our new output matches what `New-ADUser` wants to see, so we can now create new users by running this command:

```
PS C:\> import-csv .\newusers.csv |
>> select-object -property *,
>> @{name='samAccountName';expression={$_.login}},
>> @{label='Name';expression={$_.login}},
>> @{n='Department';e={$_.Dept}} |
>> new-aduser
>>
```

The syntax might be a bit ugly, but the technique is incredibly powerful. It's also usable in many other places in PowerShell, and you'll see it again in upcoming chapters. You'll even see it in the examples contained in PowerShell's help files; run `Help Select -Example` and look for yourself.

9.6 *Parenthetical commands*

Sometimes, no matter how hard you try, you can't make pipeline input work. For example, consider the `Get-WmiObject` command. You'll learn more about it in an upcoming chapter, but for now, look at the help for its `-ComputerName` property, shown in figure 9.13.

```
Administrator: Windows PowerShell
-ComputerName <String[]>
    Specifies the computer against which you want to run the
    management operation. The value can be a fully qualified domain
    name, a NetBIOS name, or an IP address. Use the local computer
    name, use localhost, or use a dot (.) to specify the local
    computer. The local computer is the default. When the remote
    computer is in a different domain from the user, you must use a
    fully qualified domain name. This parameter can also be piped to
    the cmdlet.

    This parameter does not rely on Windows PowerShell remoting,
    which uses WS-Management ). You can use the ComputerName
    parameter of Get-WmiObject even if your computer is not
    configured to run WS-Management remote commands.

    Required?           false
    Position?          named
    Default value      Local computer
    Accept pipeline input? false
    Accept wildcard characters? false

-Credential <PSCredential>
    Specifies a user account that has permission to perform this
    action. The default is the current user. Type a user name, such
    as "User01", "Domain01\User01", or User@Contoso.com. Or, enter a
    PSCredential object, such as an object that is returned by the
    Get-Credential cmdlet. When you type a user name, you will be
    prompted for a password.

    Required?           false
    Position?          named
    Default value      Current user
-- More --
```

Figure 9.13 Reading the full help for `Get-WmiObject`

This parameter doesn't accept computer names from the pipeline. How can we retrieve names from someplace—such as our text file, which contains one computer name per line—and feed them to the command? The following won't work:

```
PS C:\> get-content .\computers.txt | get-wmiobject -class win32_bios
```

The String objects produced by Get-Content won't match the -ComputerName parameter of Get-WmiObject. What can we do? Use parentheses:

```
PS C:\> Get-WmiObject -class Win32_BIOS -ComputerName (Get-Content  
➥ .\computers.txt)
```

Think back to high school algebra class, and you'll recall that parentheses mean "do this first." That's what PowerShell does: It runs the parenthetical command first. The results of that command—in this case, a bunch of String objects—are fed to the parameter. Because -ComputerName happens to want a bunch of String objects, the command works.

TRY IT NOW If you have a couple of computers for testing this, go ahead and try that command. Put the correct computer names or IP addresses into your own Computers.txt file. This works best for computers all in the same domain, because permissions are taken care of more easily in that environment.

The parenthetical command trick is powerful because it doesn't rely on pipeline parameter binding at all—it takes objects and sticks them right into the parameter. But the technique doesn't work if your parenthetical command isn't generating the exact type of object that the parameter expects, so sometimes you'll have to manipulate things a bit. Let's look at how.

9.7 Extracting the value from a single property

Earlier in this chapter, we showed you an example of using parentheses to execute Get-Content, feeding its output to the parameter of another cmdlet:

```
Get-Service -computerName (Get-Content names.txt)
```

Rather than getting your computer names from a static text file, you might want to query them from Active Directory. With the ActiveDirectory module (available on a Windows Server 2008 R2 or later domain controller, and installable with the RSAT), you could query all of your domain controllers:

```
get-adcomputer -filter * -searchbase "ou=domain controllers,  
➥ dc=company,dc=pri"
```

Could you use the same parentheses trick to feed computer names to Get-Service? For example, would this work?

```
Get-Service -computerName (Get-ADComputer -filter *  
➥ -searchBase "ou=domain controllers,dc=company,dc=pri")
```

Above and beyond

If you don't have a domain controller handy, that's OK; we'll quickly tell you what you need to know about the `Get-ADComputer` command.

First, it's contained in a module named `ActiveDirectory`. As we already mentioned, that module installs on any Windows Server 2008 R2 or later domain controller, and it's available in the RSAT to install on a client computer that belongs to a domain.

Second, the command—as you might expect—retrieves computer objects from the domain.

Third, it has two useful parameters. `-Filter *` retrieves all computers, and you can specify other filter criteria to limit the results, such as specifying a single computer name. The `-SearchBase` parameter tells the command where to start looking for computers; in this example, we're having it start in the `Domain Controllers` organizational unit (OU) of the `Company.com` domain:

```
get-adcomputer -filter * -searchbase "ou=domain controllers,  
➥dc=company,dc=pri"
```

Fourth, computer objects have a `Name` property, which contains the computers' host name.

We realize that throwing this kind of command at you—which, depending on your lab environment, you might not have access to—might be unfair. But it's an incredibly useful command for the scenarios we're looking at, and it's one you definitely want to use in a production environment. Provided you can keep the preceding four facts in mind, you should be fine for this chapter.

Sadly, it won't. Look at the help for `Get-Service`, and you'll see that the `-computerName` parameter expects `String` values.

Run this instead:

```
get-adcomputer -filter * -searchbase "ou=domain controllers,  
➥dc=company,dc=pri" | gm
```

`Get-Member` reveals that `Get-ADComputer` is producing objects of the type `ADComputer`. Those aren't `String` objects, so `-computerName` won't know what to do with them. But the `ADComputer` objects do have a `Name` property. What you need to do is extract the values of the objects' `Name` properties and feed those values, which are computer names, to the `-ComputerName` parameter.

TIP This is an important fact about PowerShell, and if you're a bit lost right now, *stop* and reread the preceding paragraphs. `Get-ADComputer` produces objects of the type `ADComputer`; `Get-Member` proves it. The `-ComputerName` parameter of `Get-Service` can't accept an `ADComputer` object; it accepts only `String` objects, as shown in its help file. Therefore, that parenthetical command won't work as written.

Once again, the `Select-Object` cmdlet can rescue you, because it includes an `-expandProperty` parameter, which accepts a property name. The cmdlet takes that property, extracts its values, and returns those values as the output of `Select-Object`. Consider this example:

```
Get-ADComputer -filter * -searchbase "ou=domain controllers,
➥dc=company,dc=pri" | Select-Object -expand name
```

You should get a simple list of computer names. Those can be fed to the `-computerName` parameter of `Get-Service` (or any other cmdlet that has a `-computerName` parameter):

```
Get-Service -computerName (Get-ADComputer -filter *
➥-searchbase "ou=domain controllers,dc=company,dc=pri" |
➥Select-Object -expand name)
```

TIP Once again, this is an important concept. Normally, a command like `Select-Object -Property Name` produces objects that happen to have only a `Name` property, because that's all we specified. The `-computerName` parameter doesn't want some random object that has a `Name` property; it wants a `String`, which is a much simpler value. `-Expand Name` goes into the `Name` property and extracts its values, resulting in simple strings being returned from the command.

Again, this is a cool trick that makes it possible to combine an even wider variety of commands with each other, saving you typing and making PowerShell do more of the work.

Now that you've seen all that coolness with `Get-ADComputer`, let's look at a similar example using commands you should have access to. We're assuming you're running the latest version of Windows, but for this example you don't need to be in a domain, or have access to a domain controller or even to a server OS. We're going to stick with the general theme of "getting computer names" because that's such a common production need.

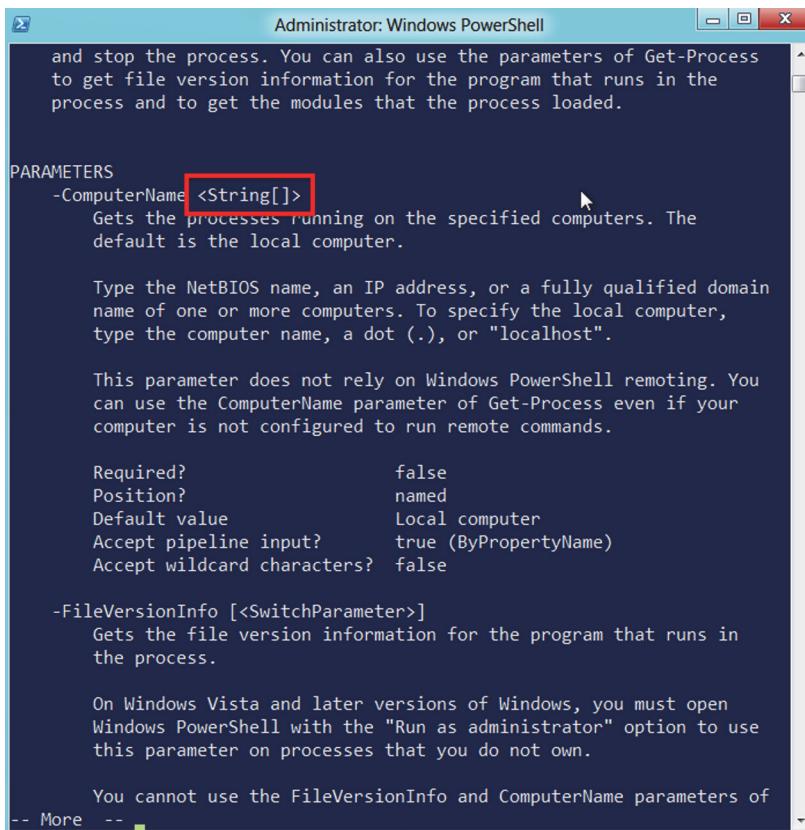

Start by creating a CSV file in Notepad that looks like the one in figure 9.14. If you provide computer names that are valid on your network, you'll be able to run the example commands. If you have only one computer, use `localhost` as the host name, and enter it three or four times. It'll still work.

hostname	operatingsystem
WIN8	windows
SERVER2	windows
CLIENT27	windows
LOCALHOST	windows

hostname,operatingsystem
WIN8,windows
SERVER2,windows
CLIENT27,windows
LOCALHOST,windows

Figure 9.14 Make sure you can import your CSV file by using `Import-CSV` and get results similar to those shown here.

Now let's say that you want to get a list of running processes from each of these computers. If you examine the help for `Get-Process`, as shown in figure 9.15, you'll see that its `-computerName` parameter does accept pipeline input `ByPropertyName`. It expects its input to be objects of the type `String`. We're not going to fuss around with pipeline input, though; we're going to focus on property extraction. The relevant information in the help file is the fact that `-ComputerName` needs one or more `String` objects.

A screenshot of a Windows PowerShell window titled "Administrator: Windows PowerShell". The window displays the help documentation for the `Get-Process` cmdlet. The help text includes examples of how to use the cmdlet, descriptions of its parameters, and detailed information about the `-ComputerName` parameter, which is highlighted with a red box. The parameter is described as accepting a `<String[]>` type and getting processes running on specified computers. It also notes that the default is the local computer and provides examples for NetBIOS names, IP addresses, and fully qualified domain names. The help text also mentions that this parameter does not rely on Windows PowerShell remoting and can be used even if the computer is not configured to run remote commands. Below the parameter description, there is a table showing its properties: Required? (false), Position? (named), Default value (Local computer), Accept pipeline input? (true (ByPropertyName)), and Accept wildcard characters? (false). Further down, the `-FileVersionInfo` parameter is described, along with a note about using it on Windows Vista and later versions of Windows. At the bottom, it states that you cannot use the `FileVersionInfo` and `ComputerName` parameters together. A "More" link is visible at the bottom left.

```

and stop the process. You can also use the parameters of Get-Process
to get file version information for the program that runs in the
process and to get the modules that the process loaded.

PARAMETERS
    -ComputerName <String[]>
        Gets the processes running on the specified computers. The
        default is the local computer.

        Type the NetBIOS name, an IP address, or a fully qualified domain
        name of one or more computers. To specify the local computer,
        type the computer name, a dot (.), or "localhost".

        This parameter does not rely on Windows PowerShell remoting. You
        can use the ComputerName parameter of Get-Process even if your
        computer is not configured to run remote commands.

    Required?           false
    Position?          named
    Default value      Local computer
    Accept pipeline input? true (ByPropertyName)
    Accept wildcard characters? false

    -FileVersionInfo [<SwitchParameter>]
        Gets the file version information for the program that runs in
        the process.

        On Windows Vista and later versions of Windows, you must open
        Windows PowerShell with the "Run as administrator" option to use
        this parameter on processes that you do not own.

        You cannot use the FileVersionInfo and ComputerName parameters of
-- More --

```

Figure 9.15 Verifying the data type needed by the `-ComputerName` parameter

Back to basics: start by seeing what Command A produces by piping it to `Get-Member`. Figure 9.16 shows the results.

`Import-CSV`'s `PSCustomObject` output isn't a `String`, so the following won't work:

```
PS C:\> Get-Process -computerName (import-csv .\computers.csv)
```

Let's try selecting the `HostName` field from the CSV, and see what that produces. You should see what's shown in figure 9.17.

You still have a `PSCustomObject`, but it has fewer properties than before. That's the point about `Select-Object` and its `-Property` parameter: It doesn't change the fact that you're outputting an entire object.

The screenshot shows a Windows PowerShell window titled "Administrator: Windows PowerShell". The command `import-csv .\computers.csv` is run, displaying a table of computer names and their operating systems:

hostname	operatingsystem
WIN8	windows
SERVER2	windows
CLIENT27	windows
LOCALHOST	windows

Then, the command `import-csv .\computers.csv | get-member` is run, showing the properties and methods of the resulting `PSCustomObject`:

Name	MemberType	Definition
Equals	Method	bool Equals(System.Object obj)
GetHashCode	Method	int GetHashCode()
GetType	Method	type GetType()
ToString	Method	string ToString()
hostname	NoteProperty	System.String hostname=WIN8
operatingsystem	NoteProperty	System.String operatingsystem=windows

Figure 9.16 Import-Csv produces objects of the type PSCustomObject.

The screenshot shows a Windows PowerShell window titled "Administrator: Windows PowerShell". The command `import-csv .\computers.csv | select -property hostname | get-member` is run, displaying the properties of the selected `PSCustomObject`:

Name	MemberType	Definition
Equals	Method	bool Equals(System.Object obj)
GetHashCode	Method	int GetHashCode()
GetType	Method	type GetType()
ToString	Method	string ToString()
hostname	NoteProperty	System.String hostname=WIN8

Figure 9.17 Selecting a single property still gives you a PSCustomObject.

The `-ComputerName` parameter can't accept a `PSCustomObject`, so this still won't work:

```
PS C:\> Get-Process -computerName (import-csv .\computers.csv |
    select -property hostname)
```

This is where the `-ExpandProperty` parameter works. Again, let's try it on its own and see what it produces, as shown in figure 9.18.

Because the `Hostname` property contains text strings, `-ExpandProperty` is able to expand those values into plain `String` objects, which is what `-ComputerName` wants. This means the following works:

```
PS C:\> Get-Process -computerName (import-csv .\computers.csv |
    select -expand hostname)
```

This is a powerful technique. It can be a little hard to grasp at first, but understanding that a property is kind of like a box can help. With `Select -Property`, you're deciding what boxes you want, but you still have boxes. With `Select -ExpandProperty`, you're extracting the contents of the box and getting rid of the box entirely. You're left with the contents.

Name	MemberType	Definition
Clone	Method	System.Object Clone()
CompareTo	Method	int CompareTo(System.Object value)
Contains	Method	bool Contains(string value)
CopyTo	Method	System.Void CopyTo(int sourceIndex, string destination, int length)
EndsWith	Method	bool EndsWith(string value), bool EndsWith(string value, StringComparison comparisonType)
Equals	Method	bool Equals(System.Object obj), bool Equals(string value, StringComparison comparisonType)
GetEnumerator	Method	System.CharEnumerator GetEnumerator()
GetHashCode	Method	int GetHashCode()
GetType	Method	type GetType()
GetTypeCode	Method	System.TypeCode GetTypeCode()
IndexOf	Method	int IndexOf(char value), int IndexOf(string value)
IndexOfAny	Method	int IndexOfAny(char[] anyOf), int IndexOfAny(string value, char[] anyOf)
Insert	Method	string Insert(int startIndex, string value)
IsNormalized	Method	bool IsNormalized(), bool IsNormalized(StringComparison comparisonType)
LastIndexOf	Method	int LastIndexOf(char value), int LastIndexOf(string value)
LastIndexOfAny	Method	int LastIndexOfAny(char[] anyOf), int LastIndexOfAny(string value, char[] anyOf)
Normalize	Method	string Normalize(), string Normalize(StringComparison comparisonType)
PadLeft	Method	string PadLeft(int totalWidth, char paddingCharacter)
PadRight	Method	string PadRight(int totalWidth, char paddingCharacter)
Remove	Method	string Remove(int startIndex, int length)
Replace	Method	string Replace(char oldChar, char newChar)
Split	Method	string[] Split(Params char[] separator, int limit, StringSplitOptions options)
StartsWith	Method	bool StartsWith(string value), bool StartsWith(string value, StringComparison comparisonType)
Substring	Method	string Substring(int startIndex, int length)
ToBoolean	Method	bool ToBoolean(System.IFormatProvider provider)
ToByte	Method	byte ToByte(System.IFormatProvider provider)

Figure 9.18 You finally have a `String` object as output!

9.8 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

Once again, we've covered a lot of important concepts in a short amount of time. The best way to cement your new knowledge is to put it to immediate use. We recommend doing the following tasks in order, because they build on each other to help remind you what you've learned and to help you find practical ways to use that knowledge.

To make this a bit trickier, we're going to force you to consider the Get-ADComputer command. Any Windows Server 2008 R2 or later domain controller has this command installed, but you don't need one. You need to know only three things:

- The Get-ADComputer command has a -filter parameter; running Get-ADComputer -filter * retrieves all computer objects in the domain.
- Domain computer objects have a Name property that contains the computer's host name.
- Domain computer objects have the type name ADComputer, which means Get-ADComputer produces objects of the type ADComputer.

That's all you need to know. With that in mind, complete these tasks.

NOTE You're not being asked to run these commands. This is more of a mental exercise. Instead, you're being asked whether these commands will function and why. You've been told how Get-ADComputer works and what it produces; you can read the help to discover what other commands expect and accept.

- 1 Would the following command work to retrieve a list of installed hotfixes from all computers in the specified domain? Why or why not? Write an explanation, similar to the ones we provided earlier in this chapter.

```
Get-Hotfix -computerName (Get-ADComputer -filter * |  
    Select-Object -expand name)
```

- 2 Would this alternative command work to retrieve the list of hotfixes from the same computers? Why or why not? Write an explanation, similar to the ones we provided earlier in this chapter.

```
Get-ADComputer -filter * | Get-HotFix
```

- 3 Would this third version of the command work to retrieve the list of hotfixes from the domain computers? Why or why not? Write an explanation, similar to the ones we provided earlier in this chapter.

```
Get-ADComputer -filter * |  
    Select-Object @{l='computername';e={$_.name}} | Get-Hotfix
```

- 4 Write a command that uses pipeline parameter binding to retrieve a list of running processes from every computer in an Active Directory (AD) domain. Don't use parentheses.

- 5 Write a command that retrieves a list of installed services from every computer in an AD domain. Don't use pipeline input; instead, use a parenthetical command (a command in parentheses).
- 6 Sometimes Microsoft forgets to add a pipeline parameter binding to a cmdlet. For example, would the following command work to retrieve information from every computer in the domain? Write an explanation, similar to the ones we provided earlier in this chapter.

```
Get-ADComputer -filter * |
  ↪Select-Object @{l='computername';e={$_.name}} |
  ↪Get-WmiObject -class Win32_BIOS
```

9.9 Further exploration

We find that many students have difficulty embracing this pipeline input concept, mainly because it's so abstract. Unfortunately, this stuff is also crucial to understanding the shell. Reread this chapter if you need to, rerun the example commands we've provided, and look super carefully at the output. For example, why is this command's output

```
Get-Date | Select -Property DayOfWeek
```

slightly different from this command's output?

```
Get-Date | Select -ExpandProperty DayOfWeek
```

If you're still not sure, drop us a line in the Forums on <http://PowerShell.org>.

9.10 Lab answers

- 1 This should work, because the nested `Get-ADComputer` expression will return a collection of computer names and the `-Computername` parameter can accept an array of values.
- 2 This won't work, because `Get-Hotfix` doesn't accept any parameters by value. It will accept `-Computername` by property name, but this command isn't doing that.
- 3 This should work. The first part of the expression is writing a custom object to the pipeline that has a `Computername` property. This property can be bound to the `Computername` parameter in `Get-Hotfix` because it accepts pipeline binding by property name.
- 4 `Get-Service -Computername (get-adcomputer -filter * |
 Select-Object -expandproperty name)`
- 5 `get-adcomputer -filter * |
 ↪Select-Object @{l='computername';e={$_.name}} |
 ↪Get-WmiObject -class Win32_BIOS`
- 6 This will not work. The `Computername` parameter in `Get-WMIObject` doesn't take any pipeline binding.

Formatting—and why it's done on the right

Let's quickly review: You know that PowerShell cmdlets produce objects, and that those objects often contain more properties than PowerShell shows by default. You know how to use `Get-Member` to get a list of all of an object's properties, and you know how to use `Select-Object` to specify the properties you want to see. Up to this point in the book, you've relied on PowerShell's default configuration and rules to determine how the final output will appear on the screen (or in a file, or in hard-copy form). In this chapter, you'll learn to override those defaults and create your own formatting for your commands' output.

10.1 Formatting: making what you see prettier

We don't want to give you the impression that PowerShell is a full-fledged management-reporting tool, because it isn't. But PowerShell has good capabilities for collecting information about computers, and, with the right output, you can certainly produce reports using that information. The trick is getting the right output, and that's what formatting is all about.

On the surface, PowerShell's formatting system can seem easy to use—and for the most part that's true. But the formatting system also contains some of the trickiest "gotchas" in the entire shell, so we want to make sure you understand how it works and why it does what it does. We're not just going to show you a few new commands here; rather, we'll explain how the entire system works, how you can interact with it, and what limitations you might run into.

10.2 Working with the default formatting

Run our old friend `Get-Process` again and pay special attention to the column headers. Notice that they don't exactly match the property names. Instead, each header has a specific width, alignment, and so forth. All that configuration stuff has to come from someplace, right? You'll find it in one of the `.format.ps1xml` files that install with PowerShell. Specifically, formatting directions for process objects are in `DotNetTypes.format.ps1xml`.

TRY IT NOW You definitely want to have PowerShell open so that you can follow along with what we're about to show you. This will help you understand what the formatting system is up to under the hood.

We'll begin by changing to the PowerShell installation folder and opening `DotNetTypes.format.ps1xml`. Be careful not to save any changes to this file. It's digitally signed, and any changes that you save—even a single carriage return or space added to the file—will break the signature and prevent PowerShell from using the file.

```
PS C:\>cd $pshome  
PS C:\>notepad dotnettypes.format.ps1xml
```

Next, find out the exact type of object returned by `Get-Process`:

```
PS C:\>get-process | gm
```

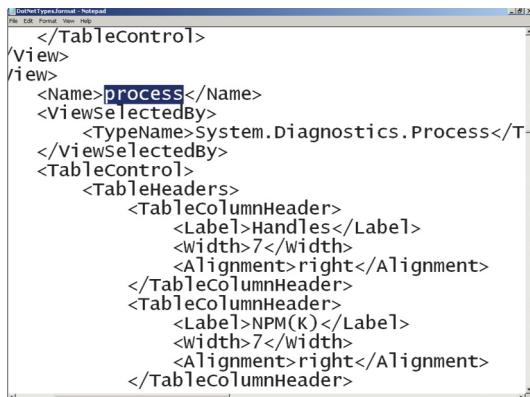

Now follow these steps:

- 1 Copy and paste the complete type name, `System.Diagnostics.Process`, to the clipboard. To do so, use your cursor to highlight the type name, and press Enter to copy it to the clipboard.
- 2 Switch over to Notepad and press Ctrl-F to open the Find window.
- 3 In the Find window, paste in the type name you copied to the clipboard. Click Find Next.
- 4 The first thing you find will probably be a `ProcessModule` object, not a `Process` object, so click Find Next again and again until you locate `System.Diagnostics.Process` in the file. Figure 10.1 shows what you should find.

What you're now looking at in Notepad is the set of directions that governs how a process is displayed by default. Scroll down, and you'll see the definition for a *table view*, which you should expect because you already know that processes display in a multi-column table. You'll see the familiar column names, and if you scroll down a bit more, you'll see where the file specifies which property will display in each column. You'll see definitions for column widths and alignments too. When you're finished browsing, close Notepad, being careful not to save any changes that you may have accidentally made to the file, and go back to PowerShell.

When you run `Get-Process`, here's what happens in the shell:

- 1 The cmdlet places objects of the type `System.Diagnostics.Process` into the pipeline.

The screenshot shows a Windows Notepad window with the title 'DotNetTypes.format - Notepad'. The content of the window is an XML document snippet:

```
</TableControl>
<view>
<view>
<Name>process</Name>
<ViewSelectedBy>
    <TypeName>System.Diagnostics.Process</Type-
</ViewSelectedBy>
<TableControl>
    <TableHeaders>
        <TablecolumnHeader>
            <Label>Handles</Label>
            <width>7</width>
            <Alignment>right</Alignment>
        </TablecolumnHeader>
        <TablecolumnHeader>
            <Label>NPM(K)</Label>
            <width>7</width>
            <Alignment>right</Alignment>
        </TablecolumnHeader>
    </TableHeaders>
```

Figure 10.1 Locating the process view in Windows Notepad

- 2 At the end of the pipeline is an invisible cmdlet called `Out-Default`. It's always there, and its job is to pick up whatever objects are in the pipeline after all of your commands have run.
- 3 `Out-Default` passes the objects to `Out-Host`, because the PowerShell console is designed to use the screen (called the *host*) as its default form of output. In theory, someone could write a shell that uses files or printers as the default output instead, but nobody has that we know of.
- 4 Most of the `Out-` cmdlets are incapable of working with standard objects. Instead, they're designed to work with special formatting instructions. So when `Out-Host` sees that it has been handed standard objects, it passes them to the formatting system.
- 5 The formatting system looks at the type of the object and follows an internal set of formatting rules (we'll cover those in a moment). It uses those rules to produce formatting instructions, which are passed back to `Out-Host`.
- 6 Once `Out-Host` sees that it has formatting instructions, it follows those instructions to construct the onscreen display.

All of this happens whenever you manually specify an `Out-` cmdlet too. For example, run `Get-Process | Out-File procs.txt`, and `Out-File` will see that you've sent it some normal objects. It will pass those to the formatting system, which creates formatting instructions and passes them back to `Out-File`. `Out-File` then constructs the text file based on those instructions. So the formatting system becomes involved anytime objects need to be converted into human-readable textual output.

What rules does the formatting system follow in step 5? For the first formatting rule, the system looks to see whether the type of object it's dealing with has a pre-defined view. That's what you saw in `DotNetTypes.format.ps1xml`: a predefined view for a `-Process` object. A few other `.format.ps1xml` files are installed with PowerShell, and they're all loaded by default when the shell starts. You can create your own pre-defined views as well, although doing so is beyond the scope of this book.

The formatting system looks for predefined views that specifically target the object type it's dealing with. In this case, it's looking for the view that handles `System.Diagnostics.Process` objects.

What if there's no predefined view? For example, try running this:

```
Get-WmiObject Win32_OperatingSystem | Gm
```

Grab that object's type name (or at least the `Win32_OperatingSystem` part), and try to find it in one of the `.format.ps1xml` files. We'll save you some time by telling you that you won't find it.

This is where the formatting system takes its next step, or what we call the *second formatting rule*. It looks to see whether anyone has declared a default display property set for that type of object. You'll find those in a different configuration file, `Types.ps1xml`. Open it in Notepad now (again, be careful not to save any changes to this file) and use the Find function to locate `Win32_OperatingSystem`. Scroll down, and you'll see `DefaultDisplayPropertySet`, shown in figure 10.2. Make a note of the six properties listed there.

Now, go back to PowerShell and run this:

```
Get-WmiObject Win32_OperatingSystem
```

Do the results look familiar? They should: The properties you see are there solely because they're listed as defaults in `Types.ps1xml`. If the formatting system finds a default display property set, it'll use that set of properties for its next decision. If it doesn't find one, the next decision will consider all of the object's properties.

That next decision—the *third formatting rule*—is about the kind of output to create. If the formatting system displays four or fewer properties, it uses a table. If there are five or more properties, it uses a list. That's why the `Win32_OperatingSystem` object wasn't displayed as a table: Its six properties trigger a list. The theory is that more than four properties might not fit well into an ad hoc table without truncating information.

```
<types>
<type>
<name>PSStandardMembers</name>
<members>
<PropertySet>
<Name>DefaultDisplayPropertySet</Name>
<ReferencedProperties>
<Name>SystemDirectory</Name>
<Name>Organization</Name>
<Name>BuildNumber</Name>
<Name>RegisteredUser</Name>
<Name>SerialNumber</Name>
<Name>Version</Name>
</ReferencedProperties>
</PropertySet>
</members>
<set>
```

Figure 10.2 Locating a DefaultDisplayPropertySet in Notepad

Now you know how the default formatting works. You also know that most cmdlets automatically trigger the formatting system, so that they can get the formatting instructions they need. Next let's look at how to control that formatting system ourselves, and override the defaults.

Oh, and by the way, the formatting system is why PowerShell sometimes seems to "lie." For example, run `Get-Process` and look at the column headers. See the one labeled `PM(K)`? Well that's a lie, sort of, because there's no property called `PM(K)`. There's a property called `PM`. The lesson here is that formatted column headers are just that—column headers. They aren't necessarily the same as the underlying property names. The only safe way to see property names is to use `Get-Member`.

10.3 Formatting tables

PowerShell has four formatting cmdlets, and we'll work with the three that provide the most day-to-day formatting capability (the fourth is briefly discussed in an "Above and beyond" section near the end of this chapter). First up is `Format-Table`, which has an alias, `Ft`.

If you read the help file for `Format-Table`, you'll notice that it has several parameters. These are some of the most useful ones, along with examples of how to use them:

- `-AutoSize`—Normally, PowerShell tries to make a table fill the width of your window (except when a predefined view, such as the one for processes, defines column widths). A table with relatively few columns will have a lot of space between those columns, which isn't always attractive. By adding the `-AutoSize` parameter, you force the shell to try to size each column to hold its contents, and no more. This makes the table "tighter" in appearance, and it will take extra time for the shell to start producing output. That's because it has to examine every object that will be formatted to find the longest values for each column. Try the following example both with and without the `-AutoSize` parameter:

```
Get-WmiObject Win32_BIOS | Format-Table -AutoSize
```

- `-Property`—This parameter accepts a comma-separated list of properties that should be included in the table. These properties aren't case-sensitive, but the shell will use whatever you type as the column headers, so you can get nicer-looking output by properly casing the property names (`CPU` instead of `cpu`, for example). This parameter accepts wildcards, meaning you can specify `*` to include all properties in the table, or something like `c*` to include all properties starting with `c`. Notice that the shell will still display only the properties it can fit in the table, so not every property you specify may display. This parameter is positional, so you don't have to type the parameter name, provided the property list is in the first position. Try these examples (the last one is shown in figure 10.3):

```
Get-Process | Format-Table -Property *
Get-Process | Format-Table -Property ID,Name,Responding -AutoSize
Get-Process | Format-Table * -AutoSize
```

Handles	NPM(K)	PM(K)	WS(K)	VM(M)	CPU(s)	Id	ProcessName

Figure 10.3 Creating an autosize table of processes

- groupBy—This parameter generates a new set of column headers each time the specified property value changes. This works well only when you've first sorted the objects on that same property. An example is the best way to see how this works:

```
Get-Service | Sort-Object Status | Format-Table -groupBy Status
```

- wrap—if the shell has to truncate information in a column, it'll end that column with ellipses (...) to visually indicate that information was suppressed. This parameter enables the shell to wrap information, which makes the table longer, but preserves all the information you want to display. Here's an example:

```
Get-Service | Format-Table Name,Status,DisplayName -autoSize -wrap
```

TRY IT NOW You should run through all of these examples in the shell, and feel free to mix and match these techniques. Experiment to see what works and what sort of output you can create.

10.4 *Formatting lists*

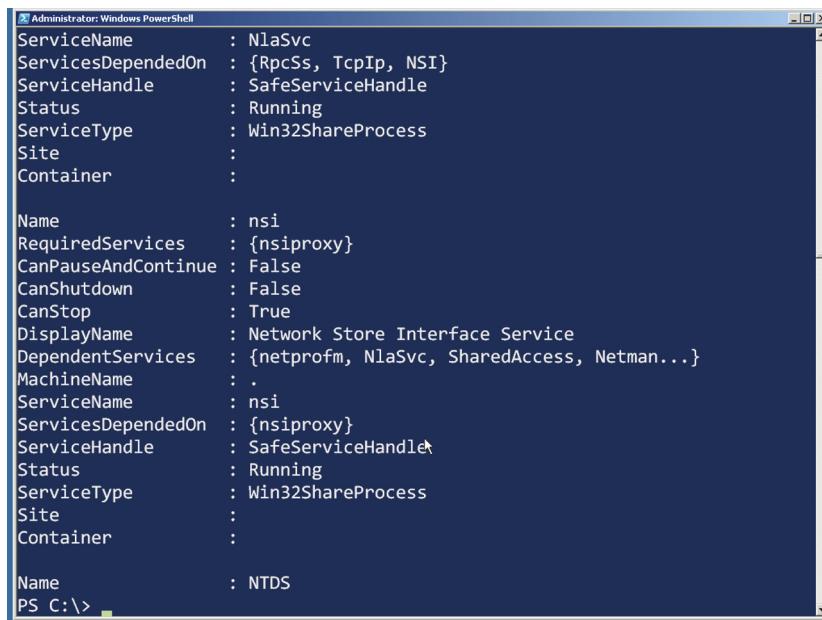

Sometimes you need to display more information than will fit horizontally in a table, which can make a list useful. `Format-List` is the cmdlet you'll turn to, or you can use its alias, `F1`.

This cmdlet supports some of the same parameters as `Format-Table`, including `-property`. In fact, `F1` is another way of displaying the properties of an object. Unlike

Gm, Fl will also display the values for those properties, so that you can see what kind of information each property contains:

```
Get-Service | Fl *
```

Figure 10.4 shows an example of the output. We often use Fl as an alternative way of discovering the properties of an object.

The screenshot shows a Windows PowerShell window titled "Administrator: Windows PowerShell". The command "Get-Service | Fl *" was run, resulting in a list of service properties. The output is as follows:

Property	Value
ServiceName	: NlaSvc
ServicesDependedOn	: {RpcSs, TcpIp, NSI}
ServiceHandle	: SafeServiceHandle
Status	: Running
ServiceType	: Win32ShareProcess
Site	:
Container	:

Status	: Running
ServiceType	: Win32ShareProcess
Site	:
Container	:
Name	: NTDS

PS C:\>

Figure 10.4 Reviewing services displayed in list form

TRY IT NOW Read the help for Format-List and try experimenting with its parameters.

10.5 Formatting wide lists

The last cmdlet, Format-Wide (or its alias, Fw), displays a wide list. It's able to display only the values of a single property, so its -property parameter accepts only one property name, not a list, and it can't accept wildcards.

By default, Format-Wide looks for an object's Name property, because Name is a commonly used property and usually contains useful information. The display generally defaults to two columns, but a -columns parameter can be used to specify more columns:

```
Get-Process | Format-Wide name -col 4
```

Figure 10.5 shows an example of what you should see.

```
Administrator: Windows PowerShell
PS C:\> get-process | format-wide name -col 4

Figure 10.5 Displaying process names in a wide list

TRY IT NOW Read the help for `Format-Wide`, and try experimenting with its parameters.

10.6 Creating custom columns and list entries

Flip back to the previous chapter and review section 9.5. In that section, we showed you how to use a hash table construct to add custom properties to an object. Both `Format-Table` and `Format-List` can use those same constructs to create custom table columns or custom list entries.

You might do this to provide a column header that's different from the property name being displayed:

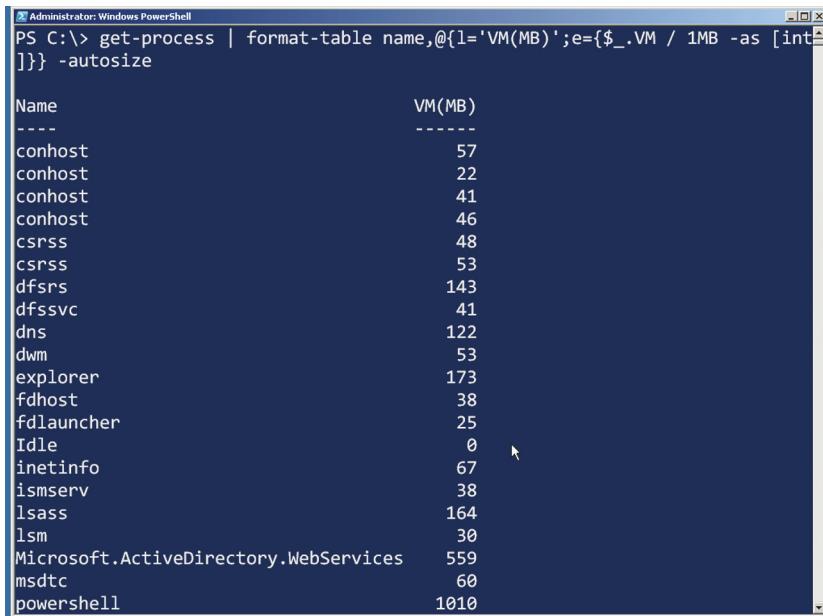

```
Get-Service |
  Format-Table @{name='ServiceName';expression=
  @{$_.Name}},Status,DisplayName
```

Or, you might put a more complex mathematical expression in place:

```
Get-Process |
  Format-Table Name,
  @{name='VM (MB)';expression={$_.VM / 1MB -as [int]}} -autosize
```

Figure 10.6 shows the output of the preceding command. We admit, we're cheating a little bit by throwing in a bunch of stuff that we haven't talked about yet. We might as well talk about it now:

- Obviously, we're starting with Get-Process, a cmdlet you're more than familiar with by now. If you run `Get-Process | Fl *`, you'll see that the `VM` property is in bytes, although that's not how the default table view displays it.
- We're telling Format-Table to start with the process's `Name` property.
- Next we're using a special hash table to create a custom column that will be labeled `VM(MB)`. That's the first part up to the semicolon, which is a separator. The second part defines the value, or expression, for that column by taking the object's normal `VM` property and dividing it by `1 MB`. The slash is PowerShell's division operator, and PowerShell recognizes the shortcuts KB, MB, GB, TB, and PB as denoting kilobyte, megabyte, gigabyte, terabyte, and petabyte, respectively.
- The result of that division operation will have a decimal component that we don't want to see. The `-as` operator enables us to change the data type of that result from a floating-point value to, in this case, an integer value (specified by `[int]`). The shell will round up or down, as appropriate, when making that conversion. The result is a whole number with no fractional component.

The screenshot shows a Windows PowerShell window titled "Administrator: Windows PowerShell". The command entered is:

```
PS C:\> get-process | format-table name,@{l='VM(MB)';e={$_.VM / 1MB -as [int]}} -autosize
```

The resulting table output is:

Name	VM(MB)
conhost	57
conhost	22
conhost	41

Figure 10.6 Creating a custom, calculated table column

We show you this little division-and-changing trick because it can be useful in creating nicer-looking output. We won't spend much more time in this book on these operations (although we'll tell you that `*` is used for multiplication, and as you might expect, `+` and `-` are for addition and subtraction, respectively).

Above and beyond

Try repeating this example:

```
Get-Process |  
Format-Table Name,  
@{name='VM(MB)';expression={$_.VM / 1MB -as [int]}} -AutoSize
```

But this time don't type it all on one line. Type it exactly as it's shown here in the book, on three lines total. You'll notice after typing the first line, which ends with a pipe character, that PowerShell changes its prompt. That's because you ended the shell in a pipe, and the shell knows that more commands are coming. It will enter this same "waiting for you to finish" mode if you hit Enter without properly closing all curly braces, quotation marks, and parentheses.

If you didn't mean to enter that extended-typing mode, hit Ctrl-C to abort, and start over. In this case, you could type the second line of text and hit Enter, and then type the third line and hit Enter. In this mode, you'll have to hit Enter one last time, on a blank line, to tell the shell you're finished. When you do so, it will execute the command as if it had been typed on a single, continuous line.

Unlike `Select-Object`, whose hash tables can accept only a `Name` and `Expression` key (although it'll also accept `N`, `L`, and `Label` for `Name`, and will accept `E` for `Expression`), the `Format-` commands can handle additional keys that are intended to control the visual display. These additional keys are most useful with `Format-Table`:

- `FormatString` specifies a formatting code, causing the data to be displayed according to the specified format. This is mainly useful with numeric and date data. Go to MSDN's Formatting Types page at ([https://msdn.microsoft.com/en-us/library/fbxft59x\(v=vs.95\).aspx](https://msdn.microsoft.com/en-us/library/fbxft59x(v=vs.95).aspx)) to review the available codes for standard numeric and date formatting, and for custom numeric and date formatting.
- `Width` specifies the desired column width.
- `Alignment` specifies the desired column alignment, either `Left` or `Right`.

Using those additional keys makes it easier to achieve the previous example's results, and even to improve them:

```
Get-Process |  
Format-Table Name,  
@{name='VM(MB)';expression={$_.VM};formatstring='F2';align='right'}  
-AutoSize
```

Now we don't have to do the division, because PowerShell will format the number as a fixed-point value having two decimal places, and it will right-align the result.

10.7 Going out: to a file, a printer, or the host

Once something is formatted, you have to decide where it'll go.

If a command line ends in a Format- cmdlet, the formatting instructions created by the Format- cmdlet go to Out-Default, which forwards them to Out-Host, which displays them on the screen:

```
Get-Service | Format-Wide
```

You could also manually pipe the formatting instructions to Out-Host, which accomplishes exactly the same thing:

```
Get-Service | Format-Wide | Out-Host
```

Alternatively, you can pipe formatting instructions to either Out-File or Out-Printer to direct formatted output to a file or to hard copy. As you'll read in section 10.9, only one of those three Out- cmdlets should ever follow a Format- cmdlet on the command line.

Keep in mind that both Out-Printer and Out-File default to a specific character width for their output, which means a hard copy or a text file might look different from an onscreen display. The cmdlets have a -width parameter that enables you to change the output width, if desired, to accommodate wider tables.

10.8 Another out: GridViews

Out-GridView provides another useful form of output. Note that this isn't technically formatting; in fact, Out-GridView entirely bypasses the formatting subsystem. No Format-cmdlets are called, no formatting instructions are produced, and no text output is displayed in the console window. Out-GridView can't receive the output of a Format-cmdlet—it can receive only the regular objects output by other cmdlets. Out-GridView may not work on non-Windows systems.

Figure 10.7 shows what the grid view looks like.

10.9 Common points of confusion

As we mentioned at the start of this chapter, the formatting system has most of the gotchas that trip up PowerShell newcomers. Our classroom students tend to run across two issues, so we'll try to help you avoid them.

10.9.1 Always format right

It's incredibly important that you remember one rule from this chapter: *format right*. Your Format- cmdlet should be the last thing on the command line, with Out-File or Out-Printer as the only exceptions. The reason for this rule is that the Format-cmdlets produce formatting instructions, and only an Out- cmdlet can properly consume those instructions. If a Format- cmdlet is last on the command line, the instructions will go to Out-Default (which is always at the end of the pipeline), which will forward them to Out-Host, which is happy to work with formatting instructions.

Figure 10.7 The results of the `Out-GridView` cmdlet

Try running this command to illustrate the need for this rule:

```
Get-Service | Format-Table | Gm
```

You'll notice, as shown in figure 10.8, that `Gm` isn't displaying information about your service objects because the `Format-Table` cmdlet doesn't output service objects. It consumes the service objects you pipe in, and it outputs formatting instructions—which is what `Gm` sees and reports on.

Now try this:

```
Get-Service | Select Name, DisplayName, Status | Format-Table |
  ConvertTo-HTML | Out-File services.html
```

Go ahead and open `Services.html` in Internet Explorer, and you'll see some crazy results. You didn't pipe service objects to `ConvertTo-HTML`; you piped formatting instructions, so that's what got converted to HTML. This illustrates why a `Format-` cmdlet, if you use one, has to be either the last thing on the command line, or the second-to-last, with the last cmdlet being `Out-File` or `Out-Printer`.

```

PS C:\>

```

Figure 10.8 Formatting cmdlets produce special formatting instructions, which aren't meaningful to humans.

Also know that `Out-GridView` is unusual (for an `Out-` cmdlet, at least) in that it *won't* accept formatting instructions and *will* accept only standard objects. Try these two commands to see the difference:

```
PS C:\>Get-Process | Out-GridView
PS C:\>Get-Process | Format-Table | Out-GridView
```

That's why we explicitly mentioned `Out-File` and `Out-Printer` as the only cmdlets that should follow a `Format-` cmdlet (technically, `Out-Host` can also follow a `Format-` cmdlet, but there's no need because ending the command line with the `Format-` cmdlet will get the output to `Out-Host` anyway).

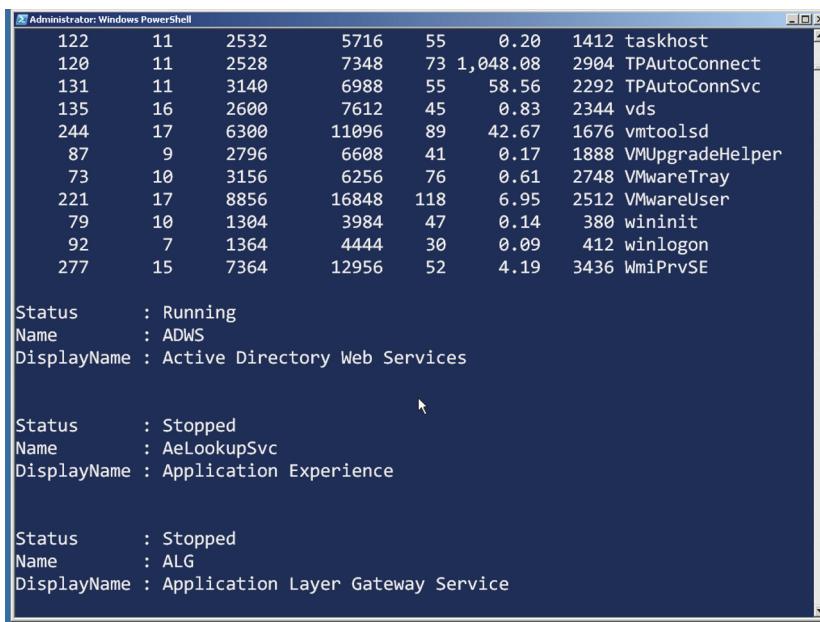

10.9.2 One type of object at a time, please

The next thing to avoid is putting multiple kinds of objects into the pipeline. The formatting system looks at the first object in the pipeline and uses the type of that object to determine what formatting to produce. If the pipeline contains two or more kinds of objects, the output won't always be complete or useful.

For example, run this:

```
Get-Process; Get-Service
```

That semicolon allows us to put two commands onto a single command line, without piping the output of the first cmdlet into the second one. This means both cmdlets

The screenshot shows a Windows PowerShell window titled "Administrator: Windows PowerShell". It displays a table of service objects followed by three separate service objects listed as if they were part of the pipeline.

Service Name	Type	Start Type	Current State	Process ID	File Path	Handle Count	Session ID

```

Figure 10.9 Putting two types of objects into the pipeline at once can confuse PowerShell's formatting system.

run independently, but they put their output into the same pipeline. As you'll see if you try this or look at figure 10.9, the output starts out fine, displaying process objects. But the output breaks down when it's time to display the service objects. Rather than producing the table you're used to, PowerShell reverts to a list. The formatting system isn't designed to take multiple kinds of objects and make the results look as attractive as possible.

What if you want to combine information drawn from two (or more) places into a single form of output? You absolutely can, and you can do so in a way that the formatting system can deal with nicely. But that's an advanced topic that we won't get to in this book.

Above and beyond

Technically, the formatting system *can* handle multiple types of objects—if you tell it how. Run `Dir | Gm` and you'll notice that the pipeline contains both `DirectoryInfo` and `FileInfo` objects. (`Gm` has no problem working with pipelines that contain multiple kinds of objects and will display member information for all of them.) When you run `Dir` by itself, the output is perfectly legible. That's because Microsoft provides a predefined custom formatting view for `DirectoryInfo` and `FileInfo` objects, and that view is handled by the `Format-Custom` cmdlet.

`Format-Custom` is mainly used to display various predefined custom views. You could technically create your own predefined custom views, but the necessary XML syntax is complicated and isn't publicly documented at this time, so custom views are limited to what Microsoft provides.

Microsoft's custom views do get a lot of usage, though. PowerShell's help information is stored as objects, for example, and the formatted help files you see on the screen are the result of feeding those objects into a custom view.

10.10 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

See if you can complete the following tasks:

- 1 Display a table of processes that includes only the process names, IDs, and whether they're responding to Windows (the `Responding` property has that information). Have the table take up as little horizontal room as possible, but don't allow any information to be truncated.
- 2 Display a table of processes that includes the process names and IDs. Also include columns for virtual and physical memory usage, expressing those values in megabytes (MB).
- 3 Use `Get-EventLog` on Windows to display a list of available event logs. (Hint: you need to read the help to learn the correct parameter to accomplish that.) Format the output as a table that includes, in this order, the log display name and the retention period. The column headers must be `LogName` and `RetDays`.
- 4 Display a list of services so that a separate table is displayed for services that are started and services that are stopped. Services that are started should be displayed first. (Hint: use a `-groupBy` parameter.)
- 5 Display a four-column-wide list of all directories in the root of the C: drive.
- 6 Create a formatted list of all .exe files in C:\Windows displaying the name, version information, and file size. PowerShell uses the `Length` property, but to make it clearer, your output should show `Size`.

10.11 Further exploration

This is the perfect time to experiment with the formatting system. Try using the three main `Format-` cmdlets to create different forms of output. The labs in upcoming chapters often ask you to use specific formatting, so you might as well hone your skills with these cmdlets and start memorizing the more often-used parameters covered in this chapter.

10.12 Lab answers

```
1 get-process | format-table Name, ID, Responding -autosize -Wrap
2 get-process | format-table Name, ID,
@{l='VirtualMB';e={$_.vm/1mb}},
@{l='PhysicalMB';e={$_.WorkingSet/1MB}} -autosize
3 Get-EventLog -List | Format-Table
@{l='LogName';e={$_.LogDisplayName}},
@{l='RetDays';e={$_.MinimumRetentionDays}} -autosize
4 Get-Service | sort Status -descending | format-table -GroupBy Status
5 Dir c:\ -directory | format-wide -column 4
6 dir c:\windows\*.exe |
➥Format-list Name, VersionInfo, @{Name="Size";Expression={$_.length}}
```

11

Filtering and comparisons

Up to this point, you've been working with whatever output the shell gave you: all the processes, all the services, all the event log entries, all the hotfixes. But this type of output isn't always going to be what you want. Often you'll want to narrow down the results to a few items that specifically interest you. That's what you'll learn to do in this chapter.

11.1 Making the shell give you just what you need

The shell offers two broad models for narrowing results, and they're both referred to as *filtering*. In the first model, you try to instruct the cmdlet that's retrieving information for you to retrieve only what you've specified. In the second model, which takes an iterative approach, you take everything the cmdlet gives you and use a second cmdlet to filter out the things you don't want.

Ideally, you'll use the first model, which we call *early filtering*, as much as possible. It may be as simple as telling the cmdlet what you're after. For example, with `Get-Service`, you can tell it which service names you want:

```
Get-Service -name e*,*s*
```

But if you want `Get-Service` to return only the running services, regardless of their names, you can't tell the cmdlet to do that for you, because it doesn't offer any parameters to specify that information.

Similarly, if you're using Microsoft's ActiveDirectory module, all of its Get-cmdlets support a `-filter` parameter. Although you can tell it `-filter *` to get all objects, we don't recommend it because of the load it can impose on a domain

controller in large domains. Instead, you can specify criteria such as the following, which explain precisely what you want:

```
Get-ADComputer -filter "Name -like '*DC'"
```

Once again, this technique is ideal because the cmdlet has to retrieve only matching objects. We call this the *filter left* technique.

11.2 Filtering left

Filter left means putting your filtering criteria as far to the left, or toward the beginning, of the command line as possible. The earlier you can filter out unwanted objects, the less work the remaining cmdlets on the command line will have to do, and the less unnecessary information will have to be transmitted across the network to your computer.

The downside of the filter-left technique is that every single cmdlet can implement its own means of specifying filtering, and every cmdlet will have varying abilities to perform filtering. With `Get-Service`, for example, you can filter only on the `Name` property of the services. But with `Get-ADComputer`, you can filter on any Active Directory attribute that a Computer object might have. Being effective with the filter-left technique requires you to learn a lot about the way various cmdlets operate, which can mean a somewhat steeper learning curve. But you'll benefit from better performance.

When you're not able to get a cmdlet to do all the filtering you need, you can turn to a core PowerShell cmdlet called `Where-Object` (which has the alias `Where`). This uses a generic syntax, and you can use it to filter any kind of object after you've retrieved it and put it into the pipeline.

To use `Where-Object`, you need to learn how to tell the shell what you want to filter, and that involves using the shell's comparison operators. Interestingly, some filter-left techniques—such as the `-filter` parameter of the `Get-` cmdlets in the Active-Directory module—use the same comparison operators, so you'll be killing two birds with one stone. But some cmdlets (we're thinking about `Get-WmiObject`, which we discuss later in the chapter) use an entirely different filtering and comparison language, which we cover when we discuss those cmdlets.

11.3 Using comparison operators

In computers, a *comparison* always takes two objects or values and tests their relationship to one another. You might be testing whether they're equal, or whether one is greater than another, or whether one of them matches a text pattern of some kind. You indicate the kind of relationship you want to test by using a *comparison operator*. The result of the test is always a Boolean value: `True` or `False`. Put another way, either the tested relationship is as you specified, or it isn't.

PowerShell uses the following comparison operators. Note that when comparing text strings, these aren't case-sensitive; an uppercase letter is seen as equal to a lowercase letter.

- `-eq`—Equality, as in `5 -eq 5` (which is True) or `"hello" -eq "help"` (which is False)
- `-ne`—Not equal to, as in `10 -ne 5` (which is True) or `"help" -ne "help"` (which is False, because they're, in fact, equal, and we're testing to see if they're unequal)
- `-ge` and `-le`—Greater than or equal to, and less than or equal to, as in `10 -ge 5` (True) or `Get-Date -le '2012-12-02'` (which will depend on when you run this, and shows how dates can be compared)
- `-gt` and `-lt`—Greater than and less than, as in `10 -lt 10` (False) or `100 -gt 10` (True)

For string comparisons, you can also use a separate set of case-sensitive operators if needed: `-ceq`, `-cne`, `-cgt`, `-clt`, `-cge`, `-cle`.

If you want to compare more than one thing at once, you can use the Boolean operators `-and` and `-or`. Each takes a subexpression on either side, and we usually enclose them in parentheses to make the line easier to read:

- `(5 -gt 10) -and (10 -gt 100)` is False, because one or both subexpressions are False
- `(5 -gt 10) -or (10 -lt 100)` is True, because at least one subexpression is True

In addition, the Boolean `-not` operator reverses True and False. This can be useful when you're dealing with a variable or a property that already contains True or False, and you want to test for the opposite condition. For example, if you want to test whether a process isn't responding, you could do the following (you'll use `$__` as a placeholder for a process object):

```
$_.Responding -eq $False
```

Windows PowerShell defines `$False` and `$True` to represent the False and True Boolean values. Another way to write that comparison is as follows:

```
-not $___.Responding
```

Because `Responding` normally contains True or False, the `-not` reverses False to True. If the process isn't responding (meaning `Responding` is False), your comparison will return True, indicating that the process is “not responding.” We prefer the second technique because it reads, in English, more like what we’re testing for: “I want to see if the process isn’t responding.” You’ll sometimes see the `-not` operator abbreviated as an exclamation mark (!).

A couple of other comparison operators are useful when you need to compare strings of text:

- `-like` accepts `*` as a wildcard, so you can compare to see if `"Hello" -like "*ll*"` (that would be True). The reverse is `-notlike`, and both are case-insensitive; use `-clike` and `-cnotlike` for case-sensitive comparisons.

- `-match` makes a comparison between a string of text and a regular expression pattern. `-notmatch` is its logical opposite, and as you might expect, `-cmatch` and `-cnotmatch` provide case-sensitive versions. Regular expressions are beyond the scope of this book.

The neat thing about the shell is that you can run almost all of these tests right at the command line (the exception is the one using the `$_` placeholder—it won’t work by itself, but you’ll see where it will work in the next section).

TRY IT NOW Go ahead and try any—or all—of these comparisons. Type them on a line—for example, `5 -eq 5`—hit Enter, and see what you get.

You can find the other available comparison operators in the `about_comparison_operators` help file, and you’ll learn about a few of the other ones in chapter 25.

Above and beyond

If a cmdlet doesn’t use the PowerShell-style comparison operators discussed in section 11.3, it probably uses the more traditional, programming language–style comparison operators that you might remember from high school or college (or even your daily work):

- `=` equality
- `<>` inequality
- `<=` less than or equal to
- `>=` greater than or equal to
- `>` greater than
- `<` less than

If Boolean operators are supported, they’re usually the words `AND` and `OR`; some cmdlets may support operators such as `LIKE` as well. For example, you’ll find support for all of these operators in the `-filter` parameter of `Get-WmiObject`; we repeat this list when we discuss that cmdlet in chapter 14.

Every cmdlet’s designers get to pick how (and if) they’ll handle filtering; you can often get examples of what they decided to do by reviewing the cmdlet’s full help, including the usage examples near the end of the help file.

11.4 Filtering objects out of the pipeline

Once you’ve written a comparison, where do you use it? Well, using the comparison language we just outlined, you can use it with the `-filter` parameter of some cmdlets, perhaps most notably the ActiveDirectory module’s `Get-` cmdlets. You can also use it with the shell’s generic filtering cmdlet, `Where-Object`.

For example, do you want to get rid of all but the running services?

```
Get-Service | Where-Object -filter { $_.Status -eq 'Running' }
```

The `-filter` parameter is positional, which means you'll often see this typed without it, and with the alias `Where`:

```
Get-Service | Where { $_.Status -eq 'Running' }
```

If you get used to reading that aloud, it sounds sensible: “where status equals running.” Here’s how it works: When you pipe objects to `Where-Object`, it examines each one of them using its filter. It places one object at a time into the `$_` placeholder and then runs the comparison to see whether it’s `True` or `False`. If it’s `False`, the object is dropped from the pipeline. If the comparison is `True`, the object is piped out of `Where-Object` to the next cmdlet in the pipeline. In this case, the next cmdlet is `Out-Default`, which is always at the end of the pipeline (as we discussed in chapter 8) and which kicks off the formatting process to display your output.

That `$_` placeholder is a special creature: You’ve seen it used before (in chapter 10), and you’ll see it in one or two more contexts. You can use this placeholder only in the specific places where PowerShell looks for it, and this happens to be one of those places. As you learned in chapter 10, the period tells the shell that you’re not comparing the entire object, but rather just one of its properties, `Status`.

We hope you’re starting to see where `Gm` comes in handy. It gives you a quick and easy way to discover the properties of an object, which lets you turn around and use those properties in a comparison like this one. Always keep in mind that the column headers in PowerShell’s final output don’t always reflect the property names. For example, run `Get-Process` and you’ll see a column like `PM(MB)`; run `Get-Process | Gm` and you’ll see that the actual property name is `PM`. That’s an important distinction: Always verify property names by using `Gm`, not with a `Format-` cmdlet.

Above and beyond

PowerShell v3 introduced a new “simplified” syntax for `Where-Object`. You can use it only when you’re doing a single comparison; if you need to compare multiple items, you still have to use the original syntax, which is what you’ve seen in this section.

Folks debate whether or not this simplified syntax is helpful. It looks something like this:

```
Get-Service | Where Status -eq 'Running'
```

Obviously, that’s a bit easier to read: It dispenses with the {curly brackets} and doesn’t require the use of the awkward-looking `$_`placeholder. But this new syntax doesn’t mean you can forget about the old syntax, which you still need for more-complex comparisons:

```
get-service | where-object {$_ .status -eq 'running' -AND  
➥ $_ .StartType -eq 'Manual'}
```

What’s more, there are years’ worth of examples out on the internet that all use the old syntax, which means you have to know it to use them. You also have to know the new syntax, because it will now start cropping up in developers’ examples. Having to know two sets of syntax isn’t exactly “simplified,” but at least you know what’s what.

11.5 Using the iterative command-line model

We want to go on a brief tangent with you now to talk about what we call the PowerShell Iterative Command-Line Model, or PSICLM. (There's no reason for it to have an acronym, but it's fun to try to pronounce.) The idea behind PSICLM is that you don't need to construct these large, complex command lines all at once and entirely from scratch. Start small.

Let's say you want to measure the amount of virtual memory being used by the 10 most virtual-memory-hungry processes. But if PowerShell itself is one of those processes, you don't want it included in the calculation. Let's take a quick inventory of what you need to do:

- 1 Get processes.
- 2 Get rid of everything that's PowerShell.
- 3 Sort the processes by virtual memory.
- 4 Keep only the top 10 or bottom 10, depending on how you sort them.
- 5 Add up the virtual memory for whatever is left.

We believe you know how to do the first three steps. The fourth is accomplished using your old friend, `Select-Object`.

TRY IT NOW Take a moment and read the help for `Select-Object`. Can you find any parameters that would enable you to keep the first or last number of objects in a collection?

We hope you found the answer.

Finally, you need to add up the virtual memory. This is where you need to find a new cmdlet, probably by doing a wildcard search with `Get-Command` or `Help`. You might try the `Add` keyword, or the `Sum` keyword, or even the `Measure` keyword.

TRY IT NOW See if you can find a command that would measure the total of a numeric property like virtual memory. Use `Help` or `Get-Command` with the `*` wildcard.

As you're trying these little tasks (and not reading ahead for the answer), you're making yourself into a PowerShell expert. Once you think you have the answer, you might start in on the iterative approach.

To start, you need to get processes. That's easy enough:

`Get-Process`

TRY IT NOW Follow along in the shell and run these commands. After each, examine the output, and see if you can predict what you need to change for the next iteration of the command.

Next, you need to filter out what you don't want. Remember, *filter left* means you want to get the filter as close to the beginning of the command line as possible. In this case, you'll use `Where-Object` to do the filtering, because you want it to be the next cmdlet.

That's not as good as having the filtering occur on the first cmdlet, but it's better than filtering later on down the pipeline.

In the shell, hit the up arrow on the keyboard to recall your last command, and then add the next command:

```
Get-Process | Where-Object -filter { $_.Name -notlike 'powershell*' }
```

You're not sure if it's powershell or powershell.exe, so you use a wildcard comparison to cover all your bases. Any process that isn't like those names will remain in the pipeline.

Run that to test it, and then hit the up arrow again to add the next bit:

```
Get-Process | Where-Object -filter { $_.Name -notlike 'powershell*' } |  
➥Sort VM -descending
```

Hitting Enter lets you check your work, and the up arrow lets you add the next piece of the puzzle:

```
Get-Process | Where-Object -filter { $_.Name -notlike 'powershell*' } |  
➥Sort VM -descending | Select -first 10
```

Had you sorted in the default ascending order, you would have wanted to keep the `-last 10` before adding this last bit:

```
Get-Process | Where-Object -filter { $_.Name -notlike 'powershell*' } |  
➥Sort VM -descending | Select -first 10 |  
➥Measure-Object -property VM -sum
```

We hope you were able to figure out at least the name of that last cmdlet, if not the exact syntax used here.

This model—running a command, examining the results, recalling it, and modifying it for another try—is what differentiates PowerShell from more-traditional scripting languages. Because PowerShell is a command-line shell, you get those immediate results, as well as the ability to quickly and easily modify your command if the results aren't what you expect. You should also be seeing the power you have when you combine even the handful of cmdlets you've learned to this point in the book.

11.6 Common points of confusion

Anytime we introduce `Where-Object` in a class, we usually come across two main sticking points. We tried to hit those concepts hard in the preceding discussion, but if you have any doubts, we'll clear them up now.

11.6.1 Filter left, please

You want your filtering criteria to go *as close to the beginning of the command line as possible*. If you can accomplish the filtering you need in the first cmdlet, do so; if not, try to filter in the second cmdlet so that the subsequent cmdlets have as little work to do as possible.

Also, try to accomplish filtering as close to the source of the data as possible. For example, if you're querying services from a remote computer and need to use

Where-Object—as we did in one of this chapter’s examples—consider using PowerShell remoting to have the filtering occur on the remote computer, rather than bringing all of the objects to your computer and filtering them there. You’ll tackle remoting in chapter 13, and we mention this idea of filtering at the source again there.

11.6.2 When \$_ is allowed

The special `$_` placeholder is valid only in the places where PowerShell knows to look for it. When it’s valid, it contains one object at a time from the ones that were piped into that cmdlet. Keep in mind that what’s in the pipeline can and will change throughout the pipeline, as various cmdlets execute and produce output.

Also be careful of nested pipelines—the ones that occur inside a parenthetical command. For example, the following can be tricky to figure out:

```
Get-Service -computername (Get-Content c:\names.txt |  
  Where-Object -filter { $_ -notlike '*dc' }) |  
  Where-Object -filter { $_.Status -eq 'Running' }
```

Let’s walk through that:

- 1 You start with `Get-Service`, but that isn’t the first command that will execute. Because of the parentheses, `Get-Content` will execute first.
- 2 `Get-Content` is piping its output—which consists of simple `String` objects—to `Where-Object`. That `Where-Object` is inside the parentheses, and within its filter, `$_` represents the `String` objects piped in from `Get-Content`. Only those strings that don’t end in `dc` will be retained and output by `Where-Object`.
- 3 The output of `Where-Object` becomes the result of the parenthetical command, because `Where-Object` was the last cmdlet inside the parentheses. Therefore, all of the computer names that don’t end in `dc` will be sent to the `-computername` parameter of `Get-Service`.
- 4 Now `Get-Service` executes, and the `ServiceController` objects it produces will be piped to `Where-Object`. That instance of `Where-Object` will put one service at a time into its `$_`placeholder, and it will keep only those services whose `-status` property is `Running`.

Sometimes we feel like our eyes are crossing with all the curly braces, periods, and parentheses, but that’s how PowerShell works, and if you can train yourself to walk through the command carefully, you’ll be able to figure out what it’s doing.

11.7 Lab

NOTE For this lab, you need a Windows 8 or Windows Server 2012, or later, computer running PowerShell v3 or later.

Remember that `Where-Object` isn’t the only way to filter, and it isn’t even the one you should turn to first. We’ve kept this chapter brief to allow you more time to work on the hands-on examples, so keeping in mind the principle of *filter left*, try to accomplish the following:

- 1 Import the NetAdapter module (available in the latest version of Windows, both client and server). Using the Get-NetAdapter cmdlet, display a list of non-virtual network adapters (adapters whose Virtual property is `False`, which PowerShell represents with the special `$False` constant).
- 2 Import the DnsClient module (available in the latest version of Windows, both client and server). Using the Get-DnsClientCache cmdlet, display a list of A and AAAA records from the cache. Hint: if your cache comes up empty, try visiting a few web pages first to force some items into the cache.
- 3 Display all EXE files under `C:\Windows\System32` that are larger than 5 MB.
- 4 Display a list of hotfixes that are security updates.
- 5 Display a list of hotfixes that were installed by the Administrator, and which are updates. If you don't have any, try finding hotfixes installed by the System account. Note that some hotfixes won't have an "installed by" value—that's OK.
- 6 Display a list of all processes running with either the name Conhost or the name Svchost.

11.8 Further exploration

Practice makes perfect, so try filtering some of the output from the cmdlets you've already learned about, such as `Get-Hotfix`, `Get-EventLog`, `Get-Process`, `Get-Service`, and even `Get-Command`. For example, you might try to filter the output of `Get-Command` to show only cmdlets. Or use `Test-Connection` to ping several computers, and show the results only from computers that didn't respond. We're not suggesting that you need to use `Where-Object` in every case, but you should practice using it when it's appropriate.

11.9 Lab answers

- 1 `import-module NetAdapter`
`get-netadapter -physical`
- 2 `Import-Module DnsClient`
`Get-DnsClientCache -type AAAA,A`
- 3 `Dir c:\windows\system32*.exe | where {$_.length -gt 5MB}`
- 4 `Get-Hotfix -Description 'Security Update'`
- 5 `get-hotfix -Description Update | where {$_.InstalledBy -match "administrator"}`
or any of these:
`get-hotfix -Description Update | where {$_.InstalledBy -match "system"}`
`get-hotfix -Description Update | where {$_.InstalledBy -eq "NT Authority\System"}`
- 6 `get-process -name svchost,conhost`

A practical interlude

It's time to put some of your new knowledge to work. In this chapter, we're not even going to try to teach you anything new. Instead, we're going to walk you through a detailed example using what you've learned. This is an absolutely real-world example: We're going to set ourselves a task, and then let you follow our thought processes as we figure out how to complete it. This chapter is the epitome of what this book is all about, because instead of just handing you the answer on how to do something, we're helping you realize that *you can teach yourself*.

12.1 Defining the task

First of all, we're assuming that you're working on Windows 10 or on Windows Server 2012 R2, or later, and that you have PowerShell v5 or later installed. The example we're going to work through may well work on earlier versions of Windows and PowerShell, but we tested on Windows 10 with PowerShell v5. We know that this won't work on Linux or macOS, because those operating systems don't have the same concept of user privilege as Windows.

Our goal is to use PowerShell to modify some of the default user privileges on the local system. These aren't permissions, exactly, but rather system-wide tasks that a user or group has the ability to perform.

12.2 Finding the commands

The first step in solving any task is to figure out which commands will do it for you. Your results might differ from ours, depending on what you have installed, but it's

the process we're going through that's important. Because we know we want to modify user privileges, we'll start with that as a keyword:

```
PS C:\> help *privilege*
Name                                Category   Module
----                                -----   -----
Update-Help                          Cmdlet    Microsoft.PowerShell.Core
ConvertTo-Csv                         Cmdlet    Microsoft.PowerShell.U...
Import-Counter                        Cmdlet    Microsoft.PowerShell.D...
about_Remote_Requirements           HelpFile
about_Remote_Troubleshooting         HelpFile
```

Hmm. That wasn't helpful. Nothing there looks like it has anything to do with privileges. OK, let's try another approach—this time, focused on commands rather than on help files, and with a search term that's a bit less specific:

```
PS C:\> get-command -noun *priv*
PS C:\>
```

OK, so there are no commands whose names contain *priv*. Disappointing! So now we have to see what might be on the online PowerShell Gallery. We'll note that this step relies on PowerShell Package Manager being installed. It's part of PowerShell v5, but you can also install it on older versions. Visit <http://powershellgallery.com> for the download links.

```
PS C:\> find-module *privilege* | format-table -auto
Version Name          Repository Description
----- ----          ----- -----
0.3.0.0 PoshPrivilege PSGallery  Module designed to use allow easi...
```

Much more promising! So let's install that module:

```
PS C:\> install-module poshprivilege
You are installing the module(s) from an untrusted repository. If you
trust this repository, change its InstallationPolicy value by
running the Set-PSRepository cmdlet.
Are you sure you want to install software from
'https://go.microsoft.com/fwlink/?LinkID=397631&clcid=0x409'?
[Y] Yes [A] Yes to All [N] No [L] No to All [S] Suspend
[?] Help(default is "N"): y
```

Now, at this point you do have to be careful. Although Microsoft runs PowerShell Gallery, it doesn't validate any of the code others publish. So we did take a break in our process, review the code that we'd just installed, and made sure we were comfortable with it before we continued. It also helps that the author of this module is a fellow MVP, Boe Prox, and we trust him.

Now let's see the commands we just gained:

```
PS C:\> get-command -module PoshPrivilege | format-table -auto
CommandType Name          Version Source
----- ----          ----- -----

```

```
Function      Add-Privilege      0.3.0.0 PoshPrivilege
Function      Disable-Privilege 0.3.0.0 PoshPrivilege
Function      Enable-Privilege  0.3.0.0 PoshPrivilege
Function      Get-Privilege     0.3.0.0 PoshPrivilege
Function      Remove-Privilege  0.3.0.0 PoshPrivilege
```

OK, those seem pretty straightforward. We need to either add or enable a privilege, so we just need to figure out which.

12.3 Learning to use the commands

With any luck, Boe included help with his module. People who write modules but don't include help are Bad People. In the sequel to this book, *Learn PowerShell Toolmaking in a Month of Lunches* (Manning, 2012), we cover how to write modules and how to put help in them—and adding help is the right thing to do. Let's see whether Boe did the right thing:

```
PS C:\> help Add-Privilege

NAME
    Add-Privilege

SYNOPSIS
    Adds a specified privilege for a user or group

SYNTAX
    Add-Privilege [[-AccountName] <String>] [-Privilege]
    <Privileges[]> [-WhatIf] [-Confirm] [<CommonParameters>]
```

He did the right thing! We haven't reproduced his entire help here, but we definitely did read it all. So it looks like we can provide a user or group name for `-AccountName`, and then we have to specify one or more privileges by name. The thing is, we don't know what they are. There's a `Get` command in the module, though, so let's try it:

```
PS C:\> Get-Privilege

Computername      Privilege          Accounts
-----            -----
DESKTOP-GDI89IG  SeAssignPrimaryTokenPrivilege {NT AUTHORITY\...
DESKTOP-GDI89IG  SeAuditPrivilege     {NT AUTHORITY\...
DESKTOP-GDI89IG  SeBackupPrivilege   {BUILTIN\Backup...
DESKTOP-GDI89IG  SeBatchLogonRight  {BUILTIN\Permiss...
DESKTOP-GDI89IG  SeChangeNotifyPrivilege {BUILTIN\Backup...
DESKTOP-GDI89IG  SeCreateGlobalPrivilege {NT AUTHORITY\...
DESKTOP-GDI89IG  SeCreatePagefilePrivilege {BUILTIN\Administrators}
```

That output goes on for several screens, but it does give us the list of privileges that are available, and not incidentally, lists everyone who already has each privilege. OK. So let's try adding one:

```
PS C:\> Add-Privilege -AccountName Administrators -Privilege SeDenyBatchLogonRight
```

Well, then. That was easy. Let's see whether it takes effect:

```
PS C:\> Get-Privilege -Privilege SeDenyBatchLogonRight
Computername      Privilege          Accounts
-----           -----
DESKTOP-GDI89IG    SeDenyBatchLogonRight {BUILTIN\Admin...}
```

It works!

Now, we freely admit that this isn't a complicated task. But the task itself isn't the point of this chapter. The point is *how we figured it out*. What did we do?

- 1 We started by searching the local help files for any that contained a specific keyword. When our search term didn't match a command name, PowerShell did a full search of all the help files' contents. That's useful, because if a file had even *mentioned* privilege, we'd have found it.
- 2 We moved on to searching for specific command names. This would help find commands *for which no help files were installed*. Ideally, commands should always have help files, but we don't live in an ideal world, so we always take this extra step.
- 3 Finding nothing locally, we searched PowerShell Gallery and found a promising-looking module. We installed the module and reviewed its commands.
- 4 Because the module author was a Good Person and had provided help, we were able to figure out how to run the commands to review a list of privileges. This helps us see how the commands' data is structured, and what sorts of values the commands are expecting. We'll often start with a Get command, if one's available, just to see what things look like.
- 5 Using the information we'd gathered to that point, we were able to implement the change we wanted.

12.4 Tips for teaching yourself

Again, the real point of this book is to teach you to teach yourself—and that's what this chapter illustrates. Here are a few tips:

- Don't be afraid of the help, and be sure to read the examples. We say that over and over, and it's like nobody believes us. We still see students, right in front of us in classes, secretly going to Google to find examples. What's so scary about the help files? If you're willing to read someone's blog, why not give the examples in the help files a shot first?
- Pay attention. Every bit of information on the screen is potentially important—don't mentally skip over the stuff that you're not immediately looking for. That's easy to do, but don't. Instead, look at each thing, and try to figure out what it's for and what information you can derive from it.
- Don't be afraid to fail. Hopefully, you have a virtual machine that you can play in—so use it. Students are constantly asking us questions like, "Hey, if I do such-and-such, what will happen?" to which we've started replying, "No idea—try it." Experimentation is good. In a virtual machine, the worst that can happen is you

have to roll back to a snapshot, right? So give it a whirl, whatever you’re working on.

- If one thing doesn’t work, don’t bang your head against a wall—try something else.

Everything gets easier with time, patience, and practice—but be sure that you’re *thinking* along the way.

12.5 Lab

NOTE For this lab, you need a Windows 8 or Windows Server 2012, or later, computer running PowerShell v3 or later.

Now it’s your turn. We’re assuming that you’re working in a virtual machine or other machine that is OK to mess up a little in the name of learning. Please don’t do this in a production environment on a mission-critical computer!

Windows 8 and Windows Server 2012 (and later) include a module for working with file shares. Your task is to create a directory called LABS on your computer and share it. For the sake of this exercise, you can assume that the folder and share don’t already exist. Don’t worry about NTFS permissions, but make sure that the share permissions are set so that Everyone has read/write access, and local Administrators have full control. Because the share will be primarily for files, you may want to set the share’s caching mode for documents. Your script should output an object showing the new share and its permissions.

12.6 Lab answer

```
#create the folder
New-item -Path C:\Labs -Type Directory | Out-Null

#create the share
$myShare = New-SmbShare -Name Labs -Path C:\Labs\ ` 
-Description "MoL Lab Share" -ChangeAccess Everyone ` 
-FullAccess Administrators -CachingMode Documents

#get the share permissions
$myShare | Get-SmbShareAccess
```

13

Remote control: one-to-one, and one-to-many

When we first started to use PowerShell (in version 1), we were playing around with the `Get-Service` command and noticed that it had a `-computerName` parameter. Hmm... does that mean it can get services from other computers too? After a bit of experimenting, we discovered that's exactly what it did. We were excited and started to look for `-computerName` parameters on other cmdlets. But we were disappointed to find there were only a few. With v2, a few more were added, but the number of commands that have this parameter is vastly outnumbered by the commands that don't.

What we've since realized is that PowerShell's creators are a bit lazy—and that's a good thing. Because they didn't want to have to code a `-computerName` parameter for every single cmdlet, they created a shell-wide system called *remoting*. This system enables you to run any cmdlet on a remote computer. In fact, you can even run commands that exist on the remote computer but that don't exist on your own computer—meaning you don't always have to install every administrative cmdlet on your workstation. This remoting system is powerful, and it offers interesting administrative capabilities.

NOTE Remoting is a huge, complex technology. We introduce you to it in this chapter and cover usage scenarios that you'll deal with 80 to 90% of the time. But we can't cover it all, so in the “Further exploration” section at the end of this chapter, we point you to a must-have resource that covers remoting's configuration options.

13.1 The idea behind remote PowerShell

Remote PowerShell works somewhat similarly to Telnet and other age-old remote-control technologies. When you run a command, it's running *on* the remote computer. Only the results of that command come back to your computer. But rather than using Telnet or Secure Shell (SSH), PowerShell uses a new communications protocol called *Web Services for Management* (WS-MAN).

WS-MAN operates entirely over HTTP or HTTPS, making it easy to route through firewalls if necessary (because each of those protocols uses a single port to communicate). Microsoft's implementation of WS-MAN comes in the form of a background service, Windows Remote Management (WinRM). WinRM is installed along with PowerShell v2 and is started by default on server operating systems such as Windows Server 2008 R2. It's installed on Windows 7 by default, but the service is disabled. It's also included with PowerShell v3 and later, and it's enabled by default on Windows Server 2012 and later (generally speaking, it's on by default on servers, and off by default on clients).

Remoting over SSH

As this book is going to print, Microsoft has announced that remoting will also be able to work over the SSH protocol, in addition to WS-MAN. That's great news for companies that already feel comfortable with SSH but aren't so sure about WS-MAN and WinRM. From a user perspective, it shouldn't make any difference in terms of how you use the remoting feature; the underlying protocol differences should be abstracted for you.

We urge you to read the documentation for `Invoke-Command` and `New-PSSessionOption` after SSH support has been released. Just know that this chapter, in this edition of the book, focuses only on the WS-MAN and WinRM approach to remoting.

You've already learned that Windows PowerShell cmdlets all produce objects as their output. When you run a remote command, its output objects need to be put into a form that can be easily transmitted over a network using the HTTP (or HTTPS) protocol. XML, it turns out, is an excellent way to do that, so PowerShell automatically *serializes* those output objects into XML. The XML is transmitted across the network and is then *deserialized* on your computer back into objects that you can work with inside PowerShell. Serialization and deserialization are really just a form of format conversion: from objects to XML (serialization), and from XML to objects (deserialization).

Why should you care how this output is returned? Because those serialized-then-deserialized objects are only snapshots, of sorts; they don't update themselves continually. For example, if you were to get the objects that represent the processes running on a remote computer, what you'd get back would be accurate for only the exact point in time at which those objects were generated. Values such as memory usage and CPU utilization won't be updated to reflect subsequent conditions. In addition, you can't tell the deserialized objects to do anything—you can't instruct one to stop itself, for example.

Those are basic limitations of remoting, but they don't stop you from doing some amazing stuff. In fact, you can tell a remote process to stop itself, but you have to be clever about it. We'll show you how later in this chapter.

To make remoting work, you have two basic requirements:

- Both your computer and the one you want to send commands to must be running Windows PowerShell v2 or later. Windows XP is the oldest version of Windows on which you can install PowerShell v2, so it's the oldest version of Windows that can participate in remoting.
- Ideally, both computers need to be members of the same domain, or of trusted/trusting domains. It's possible to get remoting to work outside a domain, but it's trickier, and we don't cover it in this chapter. To learn more about that scenario, open PowerShell and run `help about_remote_troubleshooting`.

TRY IT NOW We hope you'll be able to follow along with some of the examples in this chapter. To participate, you'll ideally have a second test computer (or a virtual machine) that's in the same Active Directory domain as the test computer you've been using up to this point. You can run any version of Windows on that second computer, provided you have PowerShell v2 or later installed. If you can't set up an additional computer or virtual machine, use `localhost` to create remoting connections to your current computer. You're still using remoting, but it isn't as exciting to be "remote controlling" the computer at which you're sitting.

13.2 WinRM overview

Let's talk about WinRM, because you're going to have to configure it in order to use remoting. Once again, you need to configure WinRM—and PowerShell remoting—on only those computers that will *receive* incoming commands. In most of the environments we've worked in, the administrators have enabled remoting on every Windows-based computer (keep in mind that PowerShell and remoting are supported all the way back to Windows XP). Doing so gives you the ability to remote into client desktop and laptop computers in the background (meaning the users of those computers won't know you're doing so), which can be tremendously useful.

WinRM isn't unique to PowerShell. Microsoft is starting to use it for more and more administrative communications—even things that use other protocols today. With that in mind, Microsoft made WinRM able to route traffic to multiple administrative applications—not only PowerShell. WinRM acts as a dispatcher: When traffic comes in, WinRM decides which application needs to deal with that traffic. All WinRM traffic is tagged with the name of a recipient application, and those applications must register as *endpoints* with WinRM so that WinRM will listen for incoming traffic on their behalf. This means you need to not only enable WinRM, but also tell PowerShell to register as an *endpoint* with WinRM. Figure 13.1 illustrates how the pieces fit together.

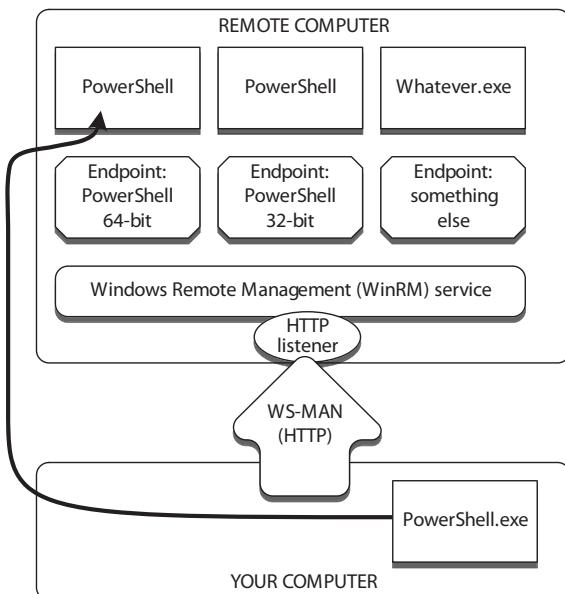

Figure 13.1 The relationship between WinRM, WS-MAN, endpoints, and PowerShell

As shown, you can have dozens or even hundreds of WinRM endpoints on your system (PowerShell calls them *session configurations*). Each endpoint can point to a different application, and you can even have endpoints that point to the same application but provide different permissions and functionality. For example, you could create a PowerShell endpoint that allows only one or two commands, and make it available to specific users in your environment. We don't dive that deep into remoting in this chapter, but chapter 23 does.

Figure 13.1 also illustrates the WinRM *listener*, which in the figure is of the HTTP variety. A listener sits and waits for incoming network traffic on behalf of WinRM—kind of like a web server listening for incoming requests. A listener “listens” on a specific port, and on a specific IP address, although the default listener created by `Enable-PSRemoting` listens on *all* local IP addresses.

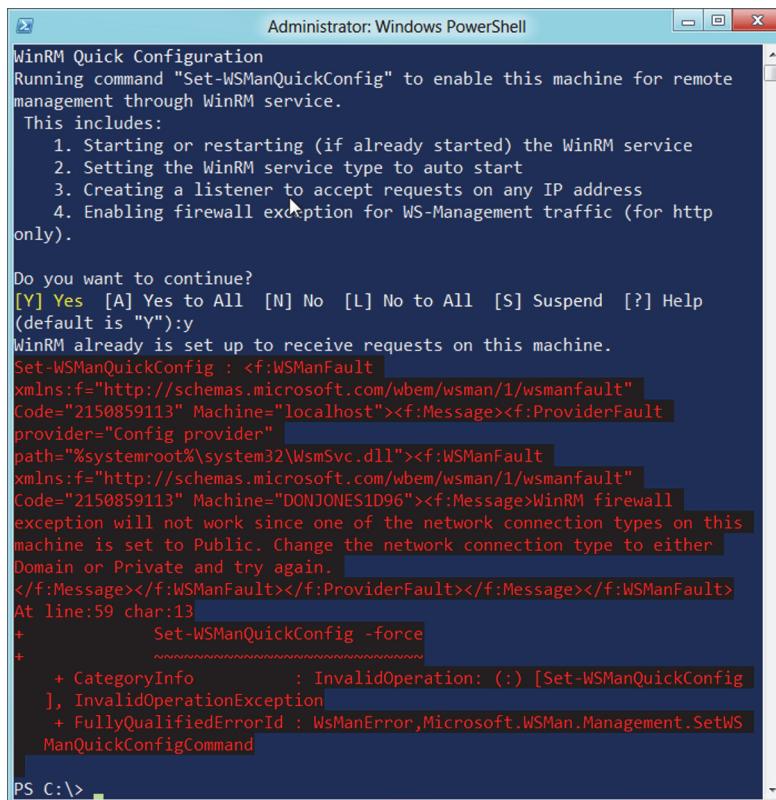

The listener connects to the defined endpoint. One way to create an endpoint is to open a copy of PowerShell—making sure that you’re running it as an administrator—and run the `Enable-PSRemoting` cmdlet. You might sometimes see references to a different cmdlet, called `Set-WSManQuickConfig`. You don’t need to run that one; `Enable-PSRemoting` will call it for you, and `Enable-PSRemoting` performs a few extra steps that are necessary to get remoting up and running. All told, the cmdlet will start the WinRM service, configure it to start automatically, register PowerShell as an endpoint, and even set up a Windows Firewall exception to permit incoming WinRM traffic.

TRY IT NOW Go ahead and enable remoting on your second computer (or on the first one, if that’s the only one you have to work with). Make sure you’re running PowerShell as an administrator (the window’s title bar should read

(Administrator). If you’re not, close the shell, right-click the PowerShell icon in the Start menu, and select Run as Administrator from the context menu. If you receive an error message when you enable remoting, stop and figure it out. You won’t be able to proceed until `Enable-PSRemoting` runs without error.

Figure 13.2 shows one of the most common errors you can get when you run `Enable-PSRemoting`.

This error typically occurs only on client computers, and the error message—once you dig into it—tells you exactly what the problem is. We have at least one network adapter set to Public. Remember that Windows Vista and later versions assign a network type—Work, Home, or Public—to each network adapter. Anything set to Public can’t have Windows Firewall exceptions, so when `Enable-PSRemoting` tries to create one, it fails. The only solution is to go into Windows and modify the network adapter setting so that whatever network you’re on is either Work or Home. But don’t do this if you’re connected to a public network (for example, a public wireless hotspot), because you’ll be turning off some valuable security protections.

```
Administrator: Windows PowerShell
WinRM Quick Configuration
Running command "Set-WSManQuickConfig" to enable this machine for remote management through WinRM service.

This includes:
  1. Starting or restarting (if already started) the WinRM service
  2. Setting the WinRM service type to auto start
  3. Creating a listener to accept requests on any IP address
  4. Enabling firewall exception for WS-Management traffic (for http only).

Do you want to continue?

Figure 13.2 The most common error you’ll get when you enable remoting on a client computer

NOTE You don't have to worry about PowerShell remoting and public networks as much on server operating systems, because they don't have the same restrictions in the OS.

If you're not excited about having to run around to every computer to enable remoting, don't worry: You can also do it with a Group Policy object (GPO). The necessary GPO settings are built into Windows Server 2008 R2 (and later) domain controllers (and you can download an ADM template from <http://download.Microsoft.com> to add these GPO settings to an older domain's domain controllers). Open a GPO and look under Computer Configuration > Administrative Templates > Windows Components. Near the bottom of the list, you'll find both Remote Shell and Windows Remote Management. For now, we'll assume you'll run `Enable-PSRemoting` on those computers that you want to configure, because at this point you're probably playing around with only a virtual machine or two.

NOTE PowerShell's `about_remote_troubleshooting` help topic provides more coverage on using GPOs. Look for the "How to enable remoting in an enterprise" and "How to enable listeners by using a Group Policy" sections within that help topic.

WinRM v2 (which is what PowerShell v2 and later use) defaults to using TCP port 5985 for HTTP, and 5986 for HTTPS. Those ports help to ensure it won't conflict with any locally installed web servers, which tend to listen to 80 and 443 instead. The default remoting setup created by `Enable-PSRemoting` sets up only the nonencrypted HTTP listener for port 5985. You can configure WinRM to use alternative ports, but we don't recommend doing so. If you leave those ports alone, all of PowerShell's remoting commands will run normally. If you change the ports, you'll have to always specify an alternative port when you run a remoting command, which means more typing for you.

If you absolutely must change the port, you can do so by running this command:

```
Winrm set winrm/config/listener?Address=*+Transport=HTTP  
→@{Port="1234"}
```

In this example, 1234 is the port you want to use. Modify the command to use HTTPS instead of HTTP to set the new HTTPS port.

DON'T TRY IT NOW Although you may want to change the port in your production environment, don't change it on your test computer. Leave WinRM using the default configuration so that the remainder of this book's examples will work for you without modification.

We should admit that there's a way to configure WinRM on client computers to use alternative default ports, which means you don't have to constantly specify an alternative port when you run commands. But for now let's stick with the defaults Microsoft came up with. You also can create multiple listeners for WinRM—say, one for HTTP

and one for encrypted HTTPS traffic, or others for different IP addresses. All of them will deliver traffic to whatever endpoints you've configured on the computer.

NOTE If you do happen to browse around in the Group Policy object settings for Remote Shell, you'll notice you can specify how long a remoting session can sit idle before the server kills it, how many concurrent users can remote into a server at once, how much memory and how many processes each remote shell can use, how many remote shells a given user can open at once, and so on. These are all great ways to help ensure your servers don't get overly burdened by forgetful administrators. By default, however, you *do* have to be an administrator to use remoting, so you don't need to worry about ordinary users clogging up your servers.

13.3 Using Enter-PSSession and Exit-PSSession for one-to-one remoting

PowerShell uses remoting in two distinct ways. The first is called *one-to-one*, or 1:1, remoting (the second is one-to-many, or 1:N, remoting, and you'll see it in the next section). With one-to-one remoting, you're accessing a shell prompt on a single remote computer. Any commands you run will run directly on that computer, and you'll see results in the shell window. This is vaguely similar to using Remote Desktop Connection, except that you're limited to the command-line environment of Windows PowerShell. This kind of remoting also uses a *fraction* of the resources that Remote Desktop requires, so it imposes much less overhead on your servers.

To establish a one-to-one connection with a remote computer, run the following command:

```
Enter-PSSession -computerName Server-R2
```

(You need to provide the correct computer name instead of Server-R2.)

Assuming that you enabled remoting on your remote computer, and you're all in the same domain, and your network is functioning correctly, you should get a connection going. PowerShell lets you know that you've succeeded by changing the shell prompt:

```
[server-r2] PS C:\>
```

The shell prompt tells you that everything you're doing is taking place on Server-R2 (or whichever server you connected to). You can run whatever commands you like. You can even import any modules or add any PSSnapins that happen to reside on that remote computer.

TRY IT NOW Try to create a remoting connection to your second computer or virtual machine. If you haven't done so, you'll also need to enable remoting on that computer before you try to connect to it. Note that you need to know the real computer name of the remote computer; WinRM won't, by default, permit you to connect by using its IP address or a DNS alias.

Your permissions and privileges carry over across the remote connection. Your copy of PowerShell will pass along whatever security token it's running under (it does this with Kerberos, so it doesn't pass your username or password across the network). Any command you run on the remote computer will run under your credentials, so you'll be able to do anything you'd normally have permission to do. It's as if you logged into that computer's console and used its copy of PowerShell directly.

Well, almost. Let's look at a couple of differences:

- Even if you have a PowerShell profile script on the remote computer, it won't run when you connect using remoting. We haven't fully covered profile scripts yet (they're in chapter 25), but suffice it to say, they're a batch of commands that run automatically each time you open the shell. Folks use them to automatically load shell extensions and modules and so forth. That doesn't happen when you remote into a computer, so be aware of that.
- You're still restricted by the remote computer's execution policy. Let's say your local computer's policy is set to `RemoteSigned`, which means you can run local, unsigned scripts. That's great, but if the remote computer's policy is set to the default, `Restricted`, it won't be running any scripts for you when you're remoting into it.

Aside from those two fairly minor caveats, you should be good to go. But wait—what do you do when you're finished running commands on the remote computer? Many PowerShell cmdlets come in pairs, with one cmdlet doing something and the other doing the opposite. In this case, if `Enter-PSSession` gets you *into* the remote computer, can you guess what would get you *out of* the remote computer? If you guessed `Exit-PSSession`, give yourself a prize. The command doesn't need any parameters; run it and your shell prompt will change back to normal, and the remote connection will close automatically.

TRY IT NOW Exit the remoting session, if you created one. We're done with it for now.

What if you forget to run `Exit-PSSession` and instead close the PowerShell window? Don't worry. PowerShell and WinRM are smart enough to figure out what you did, and the remote connection will close all by itself.

We do have one caution to offer: When you're remoting into a computer, don't run `Enter-PSSession` *from that computer* unless you fully understand what you're doing. Let's say you work on Computer A, which runs Windows 7, and you remote into Server-R2. Then, at the PowerShell prompt, you run this:

```
[server-r2] PS C:\>enter-pssession server-dc4
```

This causes Server-R2 to maintain an open connection to Server-DC4, which can start to create a *remoting chain* that's hard to keep track of, and which imposes unnecessary overhead on your servers. At times you may *have* to do this—we're thinking mainly of instances where a computer such as Server-DC4 sits behind a firewall and you can't

access it directly, so you use Server-R2 as a middleman to hop over to Server-DC4. But, as a general rule, try to avoid remote chaining.

CAUTION Some people refer to remote chaining as *the second hop*, and it's a major PowerShell gotcha. We offer a hint: If the PowerShell prompt is displaying a computer name, then you're finished. You can't issue any more remote-control commands until you exit that session and "come back" to your computer. Enabling multihop remoting is something we discuss in chapter 23.

When you're using this one-to-one remoting, you don't need to worry about objects being serialized and deserialized. As far as you're concerned, you're typing directly on the remote computer's console. If you retrieve a process and pipe it to `Stop-Process`, it'll stop running, as you'd expect it to.

13.4 Using `Invoke-Command` for one-to-many remoting

The next trick—and honestly, this is one of the coolest things in Windows PowerShell—is to send a command to *multiple remote computers at the same time*. That's right, full-scale distributed computing. Each computer will independently execute the command and send the results back to you. It's all done with the `Invoke-Command` cmdlet, and it's called *one-to-many*, or 1:N, remoting.

The command looks like this:

```
Invoke-Command -computerName Server-R2,Server-DC4,Server12
  ↪-command { Get-EventLog Security -newest 200 |
  ↪Where { $_.EventID -eq 1212 } }
```

TRY IT NOW Run this command. Substitute the name of your remote computer (or computers) where we put our three server names.

Everything in those outermost curly braces, the {}, gets transmitted to the remote computers—all three of them. By default, PowerShell talks to up to 32 computers at once; if you specify more than that, it will queue them up, and as one computer completes, the next one in line will begin. If you have an awesome network and powerful computers, you could raise that number by specifying the `-throttleLimit` parameter of `Invoke-Command`; read the command's help for more information.

Be careful about the punctuation

We need to further consider the syntax for a one-to-many remoting example, because in this case PowerShell's punctuation can get confusing. That confusion can make you do the wrong thing when you start constructing these command lines on your own.

Here's an example to consider:

```
Invoke-Command -computerName Server-R2,Server-DC4,Server12
  ↪-command { Get-EventLog Security -newest 200 |
  ↪Where { $_.EventID -eq 1212 } }
```

(continued)

Two commands in this example use curly braces: `Invoke-Command` and `Where` (which is an alias for `Where-Object`). `Where` is entirely nested within the outer set of braces. The outermost set of braces encloses everything that's being sent to the remote computers for execution:

```
Get-EventLog Security -newest 200 | Where { $_.EventID -eq 1212 }
```

Following that nesting of commands can be tough, particularly in a book like this one, where the physical width of the page makes it necessary to display the command across several lines of text.

Be sure you can identify the exact command that's being sent to the remote computer, and that you understand the use for each matched set of curly braces.

We should tell you that you won't see the `-command` parameter in the help for `Invoke-Command`, but the command we just showed you will work fine. The `-command` parameter is an *alias*, or nickname, for the `-scriptblock` parameter that you *will* see listed in the help. We have an easier time remembering `-command`, so we tend to use it instead of `-scriptblock`, but they both work the same way.

If you carefully read the help for `Invoke-Command` (see how we're continuing to push those help files?), you'll also notice a parameter that lets you specify a script file, rather than a command. That parameter lets you send an entire script from your local computer to the remote computers—meaning you can automate some complex tasks and have each computer do its own share of the work.

TRY IT NOW Make sure you can identify the `-scriptblock` parameter in the help for `Invoke-Command`, and that you can spot the parameter that would enable you to specify a file path and name instead of a script block.

We want to circle back to the `-computerName` parameter we mentioned at the beginning of the chapter. When we first used `Invoke-Command`, we typed a comma-separated list of computer names, as we did in the previous example. But we work with a lot of computers, and we don't want to have to type them all in every time. We keep text files for some of our common computer categories, such as web servers and domain controllers. Each text file contains one computer name per line, and that's it—no commas, no quotes, no nothing. PowerShell makes it easy for us to use those files:

```
Invoke-Command -command { dir }  
➥-computerName (Get-Content webservers.txt)
```

The parentheses here force PowerShell to execute `Get-Content` first—the same way parentheses work in math. The results of `Get-Content` are then stuck into the `-computerName` parameter, which works against each of the computers listed in the file.

We also sometimes want to query computer names from Active Directory, which is a bit trickier. We can use the `Get-ADComputer` command (from the `ActiveDirectory`

module; it's available in the Windows 7 Remote Server Administration Tools and on Windows Server 2008 R2 and later domain controllers) to retrieve computers, but we can't stick that command in parentheses as we did with `Get-Content`. Why not? Because `Get-Content` produces simple strings of text, which `-computerName` is expecting. `Get-ADComputer`, on the other hand, produces entire computer objects, and the `-computerName` parameter won't know what to do with them.

If we want to use `Get-ADComputer`, we need to find a way to get only the *values* from those computer objects' `Name` properties. The following example shows you how:

```
Invoke-Command -command { dir } -computerName (
    ↳Get-ADComputer -filter * -searchBase "ou=Sales,dc=company,dc=pri" |
    ↳Select-Object -expand Name )
```

TRY IT NOW If you're running PowerShell on a Windows Server 2008 R2 (or later) domain controller, or on a Windows 7 (or later) computer that has the Remote Server Administration Tools installed, you can run `Import-Module ActiveDirectory` and try the preceding command. If your test domain doesn't have a Sales OU that contains a computer account, change `ou=Sales` to `ou=Domain Controllers`, and be sure to change `company` and `pri` to the appropriate values for your domain (for example, if your domain is `mycompany.org`, you'd substitute `mycompany` for `company`, and `org` for `pri`).

Within the parentheses, we've piped the computer objects to `Select-Object`, and we've used its `-expand` parameter. We're telling it to expand the `Name` property of whatever came in—in this case, those computer objects. The result of that entire parenthetical expression will be a bunch of computer names, not computer objects—and computer names are exactly what the `-computerName` parameter wants to see.

NOTE We hope the previous discussion of the `-Expand` parameter triggered some déjà vu: You first saw that parameter in chapter 9. If you need to, flip back to that chapter for a refresher.

To be thorough, we should mention that the `-filter` parameter of `Get-ADComputer` specifies that all computers should be included in the command's output. The `-searchBase` parameter tells the command to start looking for computers in the specified location—in this case, the Sales OU of the `company.pri` domain. Again, the `Get-ADComputer` command is available only on Windows Server 2008 R2 (and later) domain controllers, and on Windows 7 (and later) client computers where you've installed the Remote Server Administration Tools (RSAT).

13.5 Differences between remote and local commands

We want to explain the differences between running commands by using `Invoke-Command` and running those same commands locally, as well as the differences between remoting and other forms of remote connectivity. For this discussion, we'll use this command as our example:

```
Invoke-Command -computerName Server-R2,Server-DC4,Server12
```

```
    -command { Get-EventLog Security -newest 200 |  
    Where { $_.EventID -eq 1212 } }
```

Let's look at some alternatives and see why they're different.

13.5.1 *Invoke-Command* vs. *-computerName*

Here's an alternative way to perform that same basic task:

```
Get-EventLog Security -newest 200  
-computerName Server-R2,Server-DC4,Server12  
| Where { $_.EventID -eq 1212 }
```

In the previous example, we used the *-computerName* parameter of *Get-EventLog*, rather than invoking the entire command remotely. We'll get more or less the same results, but there are some important differences in how this version of the command executes:

- The computers are contacted sequentially rather than in parallel, which means the command may take longer to execute.
- The output doesn't include a *PSComputerName* property, which may make it harder for us to tell which result comes from which computer.
- The connection isn't made using WinRM, but instead uses whatever underlying protocol the .NET Framework decides to use. We don't know what that is, and it might be harder to get the connection through any firewalls between us and the remote computer.
- We're querying 200 records from each of the three computers, and only then are we filtering through them to find the ones with EventID 1212. That means we're probably bringing over a lot of records we don't want.
- We're getting back event log objects that are fully functional.

These differences apply to any cmdlet that has a *-computerName* parameter. Generally speaking, it can be more efficient and effective to use *Invoke-Command* rather than a cmdlet's *-computerName* parameter.

Here's what happens if we use the original *Invoke-Command* instead:

- The computers are contacted in parallel, meaning the command can complete somewhat more quickly.
- The output includes a *PSComputerName* property, enabling us to more easily distinguish the output from each computer.
- The connection is made through WinRM, which uses a single predefined port that can make it easier to get through any intervening firewalls.
- Each computer queries the 200 records and filters them *locally*. The only data transmitted across the network is the result of that filtering, meaning that only the records we care about are transmitted.
- Before transmitting, each computer serializes its output into XML. Our computer receives that XML and deserializes it back into something that looks like

objects. But they aren't real event log objects, and that might limit what we can do with them once they're on our computer.

That last point is a big distinction between using a `-computerName` parameter and using `Invoke-Command`. Let's discuss that distinction.

13.5.2 Local vs. remote processing

We'll cite our original example again:

```
Invoke-Command -computerName Server-R2,Server-DC4,Server12
  -command { Get-EventLog Security -newest 200 |
  Where { $_.EventID -eq 1212 } }
```

Now, compare it to this alternative:

```
Invoke-Command -computerName Server-R2,Server-DC4,Server12
  -command { Get-EventLog Security -newest 200 } |
  Where { $_.EventID -eq 1212 }
```

The differences are subtle. Well, we see only one difference: We moved one of those curly braces.

In the second version, only `Get-EventLog` is being invoked remotely. All of the results generated by `Get-EventLog` are serialized and sent to our computer, where they're deserialized into objects and then piped to `Where` and filtered. The second version of the command is less efficient, because a lot of unnecessary data is being transmitted across the network, and our one computer has to filter the results from three computers, rather than those three computers filtering their own results for us. The second version, then, is a bad idea.

Let's look at two versions of another command, starting with the following:

```
Invoke-Command -computerName Server-R2
  -command { Get-Process -name Notepad } |
  Stop-Process
```

Now let's look at the second version:

```
Invoke-Command -computerName Server-R2
  -command { Get-Process -name Notepad |
  Stop-Process }
```

Once again, the only difference between these two is the placement of a curly brace. But in this example, the first version of the command won't work.

Look carefully: We're sending `Get-Process -name Notepad` to the remote computer. The remote computer retrieves the specified process, serializes it into XML, and sends it to us across the network. Our computer receives that XML, deserializes it back into an object, and pipes it to `Stop-Process`. The problem is that the serialized XML doesn't contain enough information for our computer to realize that the process came from a *remote machine*. Instead, our computer will try to stop the Notepad process *running locally*, which isn't what we want at all.

The moral of the story is to always complete as much of your processing on the remote computer as possible. The only thing you should expect to do with the results of `Invoke-Command` is to display them or store them as a report, or a data file, or so forth. The second version of our command follows that advice: What's being sent to the remote computer is `Get-Process -name Notepad | Stop-Process`, so the entire command—both getting the process and stopping it—happens on the remote computer. Because `Stop-Process` doesn't normally produce any output, there won't be any objects to serialize and send to us, so we won't see anything on our local console. But the command will do what we want: Stop the Notepad process *on the remote computer*, not on our local machine.

Whenever we use `Invoke-Command`, we always look at the commands after it. If we see commands for formatting, or for exporting data, we're fine, because it's OK to do those things with the results of `Invoke-Command`. But if `Invoke-Command` is followed by action cmdlets—ones that start, stop, set, change, or do something else—then we sit back and try to think about what we're doing. Ideally, we want all of those actions to happen on the remote computer, not on our local computer.

13.5.3 Deserialized objects

Another caveat to keep in mind about remoting is that the objects that come back to your computer aren't fully functional. In most cases, they lack methods, because they're no longer "attached" to "live" software.

For example, run this on your local computer and you'll notice that a `ServiceController` object has numerous methods associated with it:

```
PS C:\> get-service | get-member

TypeName: System.ServiceProcess.ServiceController
Name          MemberType  Definition
----          -----
Name          AliasProperty  Name = ServiceName
RequiredServices AliasProperty  RequiredServices = ServicesDep
Disposed       Event        System.EventHandler Disposed(S
Close         Method       System.Void Close()
Continue      Method       System.Void Continue()
CreateObjRef  Method       System.Runtime.Remoting.ObjRef
Dispose       Method       System.Void Dispose()
Equals        Method       bool Equals(System.Object obj)
ExecuteCommand Method      System.Void ExecuteCommand(int
GetHashCode   Method       int GetHashCode()
GetLifetimeService Method    System.Object GetLifetimeServ
GetType       Method       System.Type GetType()
InitializeLifetimeService Method  System.Object InitializeLifeti
Pause         Method       System.Void Pause()
Refresh       Method       System.Void Refresh()
Start         Method       System.Void Start(), System.Vo
Stop          Method       System.Void Stop()
WaitForStatus Method      System.Void WaitForStatus(Syst
CanPauseAndContinue Property  bool CanPauseAndContinue {get;
CanShutdown   Property  bool CanShutdown {get;}
```

```
CanStop           Property     bool CanStop {get; }
Container        Property     System.ComponentModel.IContainer
DependentServices Property     System.ServiceProcess.ServiceC
```

Now get some of those same objects via remoting:

```
PS C:\> Invoke-Command -ScriptBlock { Get-Service } -ComputerName
DONJONESE408 | Get-Member
    TypeName: Deserialized.System.ServiceProcess.ServiceController
    Name          MemberType  Definition
    ----          -----      -----
    ToString      Method     string ToString(), string ToString(string
                           format, System.I
    Name          NoteProperty System.String Name=AeLookupSvc
    PSComputerName NoteProperty System.String PSComputerName=DONJONESE408
    PSShowComputerName NoteProperty System.Boolean PSShowComputerName=True
    RequiredServices NoteProperty
                           Deserialized.System.ServiceProcess.ServiceController[] Req
    RunspaceId    NoteProperty System.Guid RunspaceId=6dc9e130-f7b2-4db4-
                           8b0d-3863033d7df
    CanPauseAndContinue Property   System.Boolean {get;set;}
    CanShutdown    Property   System.Boolean {get;set;}
    CanStop        Property   System.Boolean {get;set;}
    Container      Property   {get;set;}
    DependentServices Property
                           Deserialized.System.ServiceProcess.ServiceController[] {ge
    DisplayName    Property   System.String {get;set;}
    MachineName   Property   System.String {get;set;}
    ServiceHandle  Property   System.String {get;set;}
    ServiceName   Property   System.String {get;set;}
    ServicesDependedOn Property
                           Deserialized.System.ServiceProcess.ServiceController[] {ge
    ServiceType   Property   System.String {get;set;}
    Site          Property   {get;set;}
    Status         Property   System.String {get;set;}
```

The methods—except the universal `ToString()` method common to all objects—are gone. This is a read-only copy of the object; you can't tell it to do things like stop, pause, resume, and so forth. So any actions you want taken as the result of your command should be included in the script block that's sent to the remote computer; that way, the objects are still live and contain all of their methods.

13.6 But wait, there's more

The previous examples have all used ad hoc remoting connections, meaning that we specified computer names. If you're going to be reconnecting to the same computer (or computers) several times within a short period of time, you can create reusable, persistent connections to use instead. We cover that technique in chapter 20.

We should also acknowledge that not every company is going to allow PowerShell remoting to be enabled—at least, not right away. Companies with extremely restrictive security policies may, for example, have firewalls on all client and server computers, which would block the remoting connection. If your company is one of those, see

whether an exception is in place for Remote Desktop Protocol (RDP). We find that's a common exception, because administrators obviously need some remote connectivity to servers. If RDP is allowed, try to make a case for PowerShell remoting. Because remoting connections can be audited (they look like network logins, much like accessing a file share would appear in the audit log), they're locked down by default to permit only administrators to connect. It's not that different from RDP in terms of security risks, and it imposes much less overhead on the remote machines than RDP does.

13.7 **Remote options**

Read their help files, and you'll notice that both `Invoke-Command` and `Enter-PSSession` have a `-SessionOption` parameter, which accepts a `<PSSessionOption>` object. What's that all about?

As we just explained, both of those commands initiate a new PowerShell connection, or *session*, when they run. They do their thing and then close that session automatically for you. You can specify a set of *session options* to change the way the session is created. The `New-PSSessionOption` command does the magic. Among other things, you can use it to specify the following:

- Open, cancellation, and idle time-outs
- Elimination of the normal data stream compression or encryption
- Various proxy-related options, for when the traffic is passing through a proxy server
- Skips of the remote machine's SSL certificate, name, and other security features

For example, here's how you could open a session and skip the machine name check:

```
PS C:\> Enter-PSSession -ComputerName DONJONESE408
[+] -SessionOption (New-PSSessionOption -SkipCNCheck)
[DONJONESE408]: PS C:\Users\donjones\Documents>
```

Review the help for `New-PSSessionOption` to see what it can do for you; in chapter 20 we'll use a few of those options to accomplish some advanced remoting tasks.

13.8 **Common points of confusion**

Whenever we start using remoting in a class we're teaching, some common problems crop up over the course of the day:

- Remoting works, by default, only with the remote computer's real computer name. You can't use DNS aliases or IP addresses. In chapter 23, we discuss some of the background behind this limitation and show you how to work around it.
- Remoting is designed to be more or less automatically configured within a domain. If every computer involved, and your user account, all belong to the same domain (or trusting domains), things will typically work great. If not, you need to run `help about_remote_troubleshooting` and dig into the details. One area where you might have to do this is in remoting across domains. You

may have to do a tiny bit of configuration in order for that to work, and the help file describes it in detail.

- When you invoke a command, you’re asking the remote computer to launch PowerShell, run your command, and then close PowerShell. The next command you invoke on that same remote computer will be starting from scratch—anything that was run in the first invocation will no longer be in effect. If you need to run a whole series of related commands, put them all into the same invocation.
- Make absolutely certain that you’re running PowerShell as an administrator, particularly if your computer has User Account Control (UAC) enabled. If the account you’re using doesn’t have Administrator permissions on the remote computer, use the `-credential` parameter of `Enter-PSSession` or `Invoke-Command` to specify an alternative account that does have Administrator permissions.
- If you’re using a local firewall product other than the Windows Firewall, `Enable-PSRemoting` won’t set up the necessary firewall exceptions. You’ll need to do it manually. If your remoting connection needs to traverse a regular firewall, such as one implemented on a router or proxy, it’ll also need a manually entered exception for the remoting traffic.
- Don’t forget that any settings in a Group Policy object override anything you configure locally. We’ve seen administrators struggle for hours to get remoting to work, only to finally discover that a GPO was overriding everything they did. In some cases, a well-meaning colleague may have put a GPO into place a long time ago and forgotten it was there. Don’t assume that there’s no GPO affecting you; check to see for sure.

13.9 Lab

NOTE For this lab, you need any Windows computer running PowerShell v3 or later. Ideally, you should have two computers that are members of the same Active Directory domain, but if you have only one computer to test with, that’s fine.

It’s time to combine some of what you’ve learned about remoting with what you’ve learned in previous chapters. See if you can accomplish the following tasks:

- 1 Make a one-to-one connection with a remote computer (or with `localhost` if you have only one computer). Launch `Notepad.exe`. What happens?
- 2 Using `Invoke-Command`, retrieve a list of services that aren’t started from one or two remote computers (it’s OK to use `localhost` twice if you have only one computer). Format the results as a wide list. (Hint: it’s OK to retrieve results and have the formatting occur on your computer—don’t include the `Format-
cmdlets` in the commands that are invoked remotely.)

- 3 Use `Invoke-Command` to get a list of the top 10 processes for virtual memory (VM) usage. Target one or two remote computers, if you can; if you have only one computer, target `localhost` twice.
- 4 Create a text file that contains three computer names, with one name per line. It's OK to use the same computer name, or `localhost`, three times if you have access to only one computer. Then use `Invoke-Command` to retrieve the 100 newest Application event log entries from the computer names listed in that file.
- 5 Using `Invoke-Command`, query one or more remote computers to display the properties `ProductName`, `EditionID`, and `CurrentVersion` from the registry key `HKEY_Local_Machine\SOFTWARE\Microsoft\Windows NT\CurrentVersion\`.
(Hint: this requires you to get the property of an item.)

13.10 Further exploration

We could cover a lot more about remoting in PowerShell—enough that you'd be reading about it for *another* month of lunches. Unfortunately, some of its trickier bits aren't well documented. We suggest heading up to PowerShell.org, and more specifically to their e-book resources, where Don and fellow MVP Dr. Tobias Weltner have put together a comprehensive (and free!) *Secrets of PowerShell Remoting* mini e-book for you. The guide rehashes some of the basics you learned in this chapter, but it primarily focuses on detailed, step-by-step directions (with color screenshots) that show how to configure a variety of remoting scenarios. The guide also digs into some of the grittier details of the protocol and troubleshooting, and even has a short section on how to talk to information security people about remoting. The guide is updated periodically, so check back every few months to make sure you have the latest edition. Don't forget that you can also reach Don with your questions in the Forums at PowerShell.org.

13.11 Lab answers

- 1 `Enter-PSSession Server01`
[Server01] PS C:\Users\Administrator\Documents> Notepad
The Notepad process will launch, but there won't be any interactive process either locally or remotely. In fact, run this way, the prompt won't return until the Notepad process ends—although an alternative command to launch it is `Start-Process Notepad`.
- 2 `Invoke-Command -scriptblock {get-service | where {$_.status -eq "stopped"} } -computername Server01,Server02 | format-wide -Column 4`
- 3 `Invoke-Command -scriptblock {get-process | sort VM -Descending | Select-first 10} -computername Server01,Server02`
- 4 `Invoke-Command -scriptblock {get-eventlog -LogName Application -Newest 100} -ComputerName (Get-Content computers.txt)`
- 5 `invoke-command -scriptblock{get-itemproperty 'HKLM:\SOFTWARE\Microsoft\Windows NT\CurrentVersion\' | Select ProductName,EditionID,CurrentVersion} -computername Server01, Server02`

Using Windows Management Instrumentation and CIM

We've been looking forward to writing this chapter, and dreading it at the same time. Windows Management Instrumentation (WMI) is probably one of the best things Microsoft has ever offered to administrators. It's also one of the worst things the company has ever inflicted on us. WMI offers a way to gather an amazing amount of system information from a computer. But it can sometimes feel arcane, and the documentation is far from user friendly. In this chapter, we introduce you to WMI the PowerShell way, showing you how it works and explaining some of its less beautiful aspects, to provide you with full disclosure on what you're up against.

We want to emphasize that WMI is an external technology; PowerShell merely interfaces with it. The focus in this chapter is on how PowerShell does that, and not on the underlying guts of WMI itself. If you'd like to explore WMI further, we offer some suggestions at the end of this chapter. Keep in mind that PowerShell v3 has made some amazing strides in minimizing how much you have to touch WMI yourself, which greatly improves the situation.

We should also emphasize that WMI stands for *Windows* Management Instrumentation; it's specific to Windows, and doesn't exist on Linux or macOS. There's something called *Open* Management Instrumentation, or OMI, which is available on some Linux builds, but as we're writing this edition of the book, PowerShell on Linux and macOS doesn't interact with OMI.

14.1 WMI essentials

A typical Windows computer contains tens of thousands of pieces of management information, and WMI seeks to organize that into something that's approachable and more or less sensible.

At the top level, WMI is organized into *namespaces*. Think of a namespace as a sort of folder that ties to a specific product or technology. For example, the root\CIMv2 namespace contains all of the Windows operating system and computer hardware information; the root\MicrosoftDNS namespace includes all of the information about DNS Server (assuming you've installed that role on your computer). On client computers, root\SecurityCenter contains information about firewall, antivirus, and antispyware utilities.

NOTE The contents of root\SecurityCenter will differ depending on what's installed on your computer, and newer versions of Windows use root\SecurityCenter2 instead, which is one example of how confusing WMI can be.

Figure 14.1 shows some of the namespaces on our computer. We generated this by using the WMI Control snap-in for the Microsoft Management Console (MMC).

Within a namespace, WMI is divided into a series of classes. A *class* represents a management component that WMI knows how to query. For example, the Antivirus-Product class in root\SecurityCenter is designed to hold information about antispyware products; the Win32_LogicalDisk class in root\CIMv2 is designed to hold information about logical disks. But even though a class exists on a computer doesn't mean that the computer has any of those components: The Win32_TapeDrive class is present on all versions of Windows, whether or not a tape drive is installed.

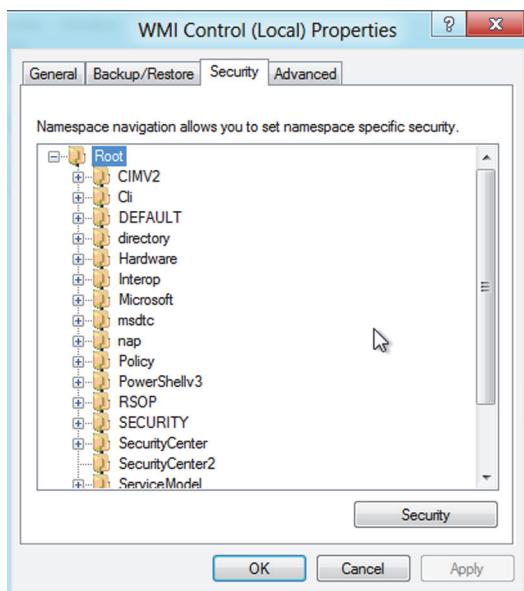

Figure 14.1 Browsing the WMI namespaces

NOTE Once again, not every computer contains the same WMI namespaces or classes. For example, newer Windows computers have a Root\SecurityCenter2 namespace in addition to the Root\SecurityCenter namespace; the former, on newer computers, contains all the good stuff.

Let's look at a quick example of querying the AntiSpywareProduct from root\SecurityCenter2 so you can see the instance that's returned:

```
PS C:\> Get-CimInstance -Namespace root\securitycenter2 -ClassName antispywareproduct
```

NOTE This example requires PowerShell v3, and we'll explain the Get-CimInstance command in just a bit.

When you have one or more manageable components, you'll have an equal number of instances for that class. An *instance* is a real-world occurrence of something represented by a class. If your computer has a single BIOS (and they all do), you'll have 1 instance of Win32_BIOS in root\CIMv2; if your computer has 100 background services installed, you'll have 100 instances of Win32_Service. Note that the class names in root\CIMv2 tend to start with either Win32_ (even on 64-bit machines) or CIM_ (which stands for *Common Information Model*, the standard upon which WMI is built). In other namespaces, those class name prefixes aren't usually used. Also, it's possible for class names to be duplicated across namespaces. It's rare, but WMI allows for it, because each namespace acts as a kind of container and boundary. When you're referring to a class, you'll also have to refer to its namespace, so that WMI knows where to look for the class and so that it doesn't get confused between two classes that have the same name but live in different namespaces.

All of these instances and classes and whatnot live in something called the *WMI repository*. In older versions of Windows, the repository could sometimes become corrupted and unusable, and you would have to rebuild it; that's less common since Windows 7.

On the surface, using WMI seems fairly simple: You figure out which class contains the information you want, query that class's instances from WMI, and then examine the instances' properties to see the management information. In some cases, you may ask an instance to execute a method in order to initiate an action or start a configuration change.

14.2 The bad news about WMI

Unfortunately, for most of its life (the situation has recently changed), Microsoft didn't exercise a lot of internal control over WMI. The company established a set of programming standards, but the product groups were more or less left to their own devices when determining how to implement classes and whether to document them. The result is that WMI can be a confusing mishmash.

Within the root\CIMv2 namespace, for example, few classes have any methods that allow you to change configuration settings. Properties are read-only, meaning that you

must have a method to make changes; if a method doesn't exist, you can't use WMI to make changes for that class. When the IIS team adopted WMI (for IIS version 6), they implemented parallel classes for a lot of elements. A website, for example, could be represented by one class that had the typical read-only properties, but also by a second class that had writable properties you could change—confusing. This confusion was made worse by the lack of good documentation on using those classes, because the IIS team originally intended them to be used mainly by their own tools, not directly by administrators. The IIS team has since backed away from WMI as a management interface, and since v7.5 has focused on PowerShell cmdlets and a PSPProvider instead.

Microsoft doesn't have a rule that says a product *has* to use WMI, or that if it does use WMI it must expose every possible component through WMI. Microsoft's DHCP server is inaccessible to WMI, as is its old WINS server. Although you can query the configuration of a network adapter, you can't retrieve its link speed, because that information isn't supplied. Although most of the Win32_ classes are well documented, few of the classes in other namespaces are documented at all. WMI isn't searchable, so the process of finding the class you need can be time-consuming and frustrating (although we'll try to help with that in the next section).

The good news is that Microsoft is making an effort to provide PowerShell cmdlets for as many administration tasks as possible. For example, WMI used to be the only practical way to programmatically restart a remote computer, using a method of the Win32_OperatingSystem class. Now, PowerShell provides a `Restart-Computer` cmdlet. In some cases, cmdlets use WMI internally, but you won't have to deal with WMI directly in those cases. Cmdlets can provide a more consistent interface for you, and they're almost always better documented. WMI isn't going away, but over time you'll probably have to deal with it—and its eccentricities—a lot less.

In fact, starting in PowerShell v3 (particularly on the newest versions of Windows, from Windows 8 or Windows Server 2012 and onward) you'll notice a lot of CIM commands, as shown in figure 14.2 (which shows the partial output of `Get-Command`). In most cases, these are “wrappers” around a piece of WMI, giving you a more PowerShell-centric way of interacting with WMI. You use these as you would any command, including asking for help, which makes them more consistent with the rest of PowerShell and helps to hide some of the underlying WMI eccentricities.

14.3 Exploring WMI

Perhaps the easiest way to get started with WMI is to put PowerShell aside for a second and explore WMI on its own. We use a free WMI Explorer tool. Unfortunately, these tools come and go like the seasons, and so we're hesitant to point to any one in particular. Just hit your favorite search engine for *WMI explorer* and see what comes up. You can try <http://powershell.org/wp/2013/03/08/wmi-explorer/> also. We locate most of what we need in WMI with this kind of tool. It does require a lot of browsing and patience—we're not pretending this is a perfect process—but it eventually gets us there.

Figure 14.2 The CIM commands are wrappers around WMI classes.

Because each computer can have different WMI namespaces and classes, you should run the tool directly on whatever computer you’re planning to query, so that you can see that computer’s WMI repository.

Let’s say we need to query a bunch of client computers to see what their icon spacing is set to. That’s a task related to the Windows desktop, and it’s a core part of the operating system, so we start in the root\CLIVM2 class, shown in the tree view on the left side of our WMI Explorer (see figure 14.3). Clicking the namespace brings up a list of its classes in the right side, and we take a guess on *Desktop* as a keyword. Scrolling to the right, we eventually find *Win32_Desktop* and click that. Doing so enables the details pane at the bottom, and we click the Properties tab to see what’s available. About a third of the way down, we find *IconSpacing*, which is listed as an integer.

Obviously, search engines are another good way to find the class you want. We tend to prefix queries with *wmi*, as in *wmi icon spacing*, and that will often pull up an example or two that can point us in the right direction. The example might be VBScript

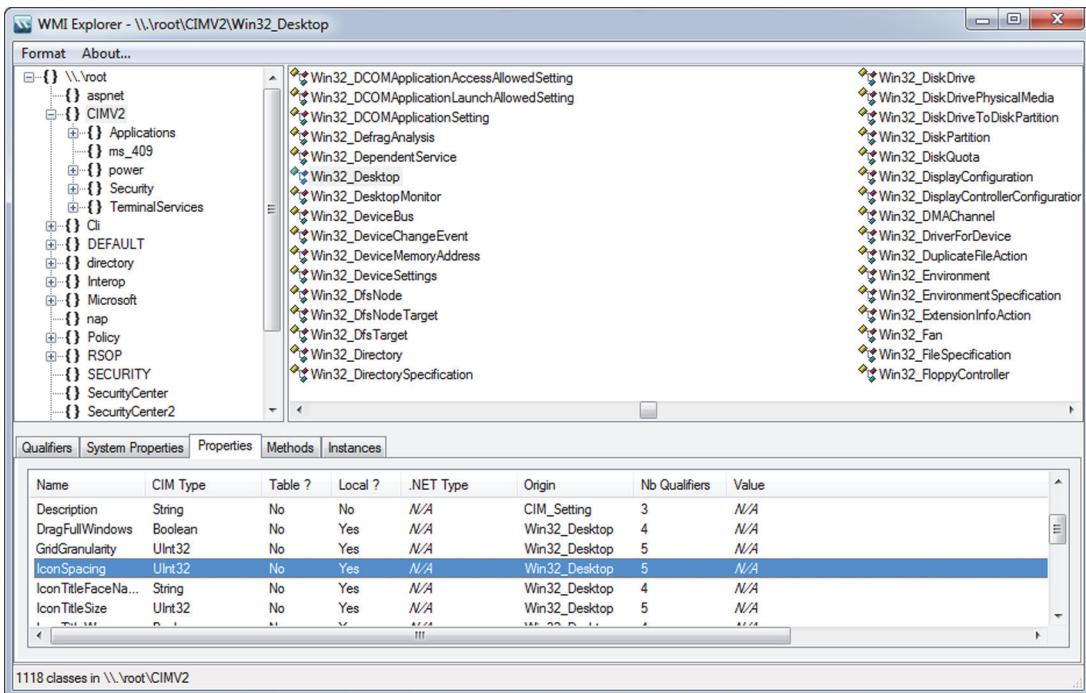

Figure 14.3 WMI Explorer

related, or might even be in a .NET language such as C# or Visual Basic, but that's OK because we're only after the WMI class name. For example, we search for *wmi icon spacing* and turn up <http://stackoverflow.com/questions/202971/-formula-or-api-for-calculating-desktop-icon-spacing-on-windows-xp> as the first result. On that page we find some C# code:

```
ManagementObjectSearcher searcher = new
    ➔ManagementObjectSearcher("root\\CIMv2", "SELECT * FROM
    ➔ Win32/Desktop");
```

We have no idea what any of that means, but `Win32/Desktop` looks like a WMI class name. Our next search is for that class name, because such a search will often turn up whatever documentation exists. We'll cover the documentation a bit later in this chapter.

Another approach is to use PowerShell itself. For example, suppose we want to do something with disks. We start by guessing at the right namespace, but we happen to know that `root\CIMv2` contains all of the core OS and hardware stuff, so we run this command:

```
PS C:\> Get-WmiObject -Namespace root\CIMv2 -list |
>> where name -like '*dis*'
>>
```

NameSpace: ROOT\CIMv2		
Name	Methods	Properties
---	-----	-----
CIM_LogicalDisk	{SetPowerState, R...}	{Access, Avail...
Win32_LogicalDisk	{SetPowerState, R...}	{Access, Avail...
Win32_MappedLogicalDisk	{SetPowerState, R...}	{Access, Avail...
CIM_DiskPartition	{SetPowerState, R...}	{Access, Avail...
Win32_DiskPartition	{SetPowerState, R...}	{Access, Avail...
CIM_DiskDrive	{SetPowerState, R...}	{Availability,...
Win32_DiskDrive	{SetPowerState, R...}	{Availability,...
CIM_DisketteDrive	{SetPowerState, R...}	{Availability,...
CIM_DiskSpaceCheck	{Invoke}	{AvailableDisk...
Win32_LogicalDiskRootDirectory	{}	{GroupComponen...
Win32_DiskQuota	{}	{DiskSpaceUsed...
Win32_LogonSessionMappedDisk	{}	{Antecedent, D...
CIM_LogicalDiskBasedOnPartition	{}	{Antecedent, D...
Win32_LogicalDiskToPartition	{}	{Antecedent, D...
CIM_LogicalDiskBasedOnVolumeSet	{}	{Antecedent, D...
Win32_DiskDrivePhysicalMedia	{}	{Antecedent, D...
CIM_RealizesDiskPartition	{}	{Antecedent, D...
Win32_DiskDriveToDiskPartition	{}	{Antecedent, D...
Win32_OfflineFilesDiskSpaceLimit	{}	{AutoCacheSize...
Win32_PerfFormattedData_Counters...	{}	{Caption, Desc...
Win32_PerfRawData_Counters_Files...	{}	{Caption, Desc...
Win32_PerfFormattedData_PerfDisk...	{}	{AvgDiskBytesP...

Eventually, we find `Win32_LogicalDisk`.

NOTE The classes whose names start with `CIM_` are often *base* classes, and you don't use them directly. The `Win32_` versions of the classes are Windows-specific. Also note that the `Win32_` prefix is used only in this particular namespace—other namespaces don't prefix class names that way.

14.4 Choose your weapon: WMI or CIM

In PowerShell v3 and later, you have two ways to interact with WMI:

- *The so-called WMI cmdlets, such as Get-WmiObject and Invoke-WmiMethod*—These are legacy cmdlets, meaning they still work, but Microsoft isn't investing in further development of them. They communicate over remote procedure calls (RPCs), which can pass through a firewall only if that firewall is patient and supports stateful inspection (in other words, it's hard).
- *The newer CIM cmdlets, such as Get-CimInstance and Invoke-CimMethod*—These are more or less equivalent to the old WMI cmdlets, although they communicate over WS-MAN (implemented by the Windows Remote Management, or WinRM, service) instead of using RPCs. This is Microsoft's way forward, and running `Get-Command -noun CIM*` reveals that Microsoft offers a lot more functionality through these commands.

Make no mistake: All of these commands use the same WMI back end (the *repository*). The main difference is in how they communicate, and in how you use them. On older

systems that don't have PowerShell installed, or that don't have WinRM enabled, the WMI cmdlets often still work (the technology was introduced for Windows NT 4.0 SP3 and later). For newer systems with PowerShell installed and WinRM enabled, the CIM cmdlets provide the best experience—and Microsoft will continue building their functionality and making performance improvements. In fact, in Windows Server 2012 R2 and later, the “old” WMI stuff is disabled by default, so stick with CIM when you can. Additionally, the CIM cmdlets can connect using the older RPC (or DCOM) protocol, so you can use *just* those cmdlets if you prefer, even when talking to older machines.

14.5 Using Get-WmiObject

With the `Get-WmiObject` cmdlet, you can specify a namespace, a class name, and even the name of a remote computer—and alternative credentials, if needed—to retrieve all instances of that class from the computer specified.

You can even provide filter criteria if you want fewer than all instances of the class. You can get a list of classes from a namespace. Here's the syntax:

```
Get-WmiObject -namespace root\cimv2 -list
```

Note that namespace names use a backslash, not a forward slash.

To retrieve a class, specify the namespace and class name:

```
Get-WmiObject -namespace root\cimv2 -class win32_desktop
```

The `root\CIMv2` namespace is the system default namespace on Windows XP Service Pack 2 and later, so if your class is in that namespace, you don't need to specify it. Also, the `-class` parameter is positional, so if you provide the class name in the first position, the cmdlet works the same.

Here are two examples, including one that uses the `gwmi` alias instead of the full cmdlet name:

```
PS C:\> Get-WmiObject win32_desktop
PS C:\> gwmi antispywareproduct -namespace root\securitycenter2
```

TRY IT NOW You should start following along at this point, running each of the commands we show you. For commands that include a remote computer name, you can substitute `localhost` if you don't have another remote computer that you can test against.

For many WMI classes, PowerShell has configuration defaults that specify which properties are shown. `Win32_OperatingSystem` is a good example because it displays only six of its properties, in a list, by default. Keep in mind that you can always pipe the WMI objects to `Get-Member` or to `Format-List *` to see all of the available properties; `Get-Member` will also list available methods. Here's an example:

```
PS C:\> Get-WmiObject win32_operatingsystem | gm
TypeName: System.Management.ManagementObject#root\cimv2\Win32_Operating
System
```

Name	MemberType	Definition
Reboot	Method	System.Manageme...
SetDateTime	Method	System.Manageme...
Shutdown	Method	System.Manageme...
Win32Shutdown	Method	System.Manageme...
Win32ShutdownTracker	Method	System.Manageme...
BootDevice	Property	System.String Bo...
BuildNumber	Property	System.String Bu...
BuildType	Property	System.String Bu...
Caption	Property	System.String Ca...
CodeSet	Property	System.String Co...
CountryCode	Property	System.String Co...
CreationClassName	Property	System.String Cr...

We truncated this output to save space, but you'll see the whole thing if you run the same command.

The `-filter` parameter lets you specify criteria for retrieving specific instances. This can be a bit tricky to use, so here's an example of its worst-case use:

```
PS C:\> gwmi -class win32_desktop -filter "name='COMPANY\\Administrator'"
```

<u>__GENUS</u>	:	2
<u>__CLASS</u>	:	Win32_Desktop
<u>__SUPERCLASS</u>	:	CIM_Setting
<u>__DYNASTY</u>	:	CIM_Setting
<u>__RELPATH</u>	:	Win32_Desktop.Name="COMPANY\\Administrator"
<u>__PROPERTY_COUNT</u>	:	21
<u>__DERIVATION</u>	:	{CIM_Setting}
<u>__SERVER</u>	:	SERVER-R2
<u>__NAMESPACE</u>	:	root\cimv2
<u>__PATH</u>	:	\\\SERVER-R2\root\cimv2:Win32_Desktop.Name="COMPANY\\Administrator"
BorderWidth	:	1
Caption	:	
CoolSwitch	:	
CursorBlinkRate	:	530
Description	:	
DragFullWindows	:	False
GridGranularity	:	
IconSpacing	:	43
IconTitleFaceName	:	Tahoma
IconTitleSize	:	8
IconTitleWrap	:	True
Name	:	COMPANY\Administrator

ScreenSaverActive	:	False
ScreenSaverExecutable	:	
ScreenSaverSecure	:	
ScreenSaverTimeout	:	
SettingID	:	
Wallpaper	:	
WallpaperStretched	:	True
WallpaperTiled	:	False

You should notice a few things about this command and its output:

- The filter criteria are usually enclosed in double quotation marks.
- The filter comparison operators aren't the standard PowerShell `-eq` or `-like` operators. Instead, WMI uses more traditional, programming-like operators, such as `=`, `>`, `<`, `<=`, `>=`, and `<>`. You can use the keyword `LIKE` as an operator, and when you use your comparison value, you have to use `%` as a character wildcard, as in `"NAME LIKE '%administrator%'`. Note that you can't use `*` as a wildcard, as you can elsewhere in PowerShell.
- String comparison values are enclosed in single quotation marks, which is why the outermost quotes that contain the entire filter expression must be double quotes.
- Backslashes are escape characters for WMI, so when you need to use a literal backslash, as in this example, you have to use two backslashes instead.
- The output of `Gwmi` always includes numerous system properties. PowerShell's default display configuration often suppresses these, but they are displayed if you deliberately list all properties, or if the class doesn't have a default. System property names start with a double underscore. Here are two particularly useful ones:
 - `__SERVER` contains the name of the computer from which the instance was retrieved. This can be useful when retrieving WMI information from multiple computers at once. This property is duplicated in the easier-to-remember `PSCoputerName` property.
 - `__PATH` is an absolute reference to the instance itself, and it can be used to requery the instance if necessary.

The cmdlet can retrieve not only from remote computers but also from multiple computers, using any technique that can produce a collection of strings that contains either computer names or IP addresses. Here's an example:

```
PS C:\> Gwmi Win32_BIOS -comp server-r2,server3,dc4
```

Computers are contacted sequentially, and if one computer isn't available, the cmdlet will produce an error, skip that computer, and move on to the next. Unavailable computers generally must time out, which means the cmdlet will pause for about 30–45 seconds until it gives up, produces the error, and moves on.

Once you retrieve a set of WMI instances, you can pipe them to any `-Object`-cmdlet, to any `Format-` cmdlet, or to any of the `Out-`, `Export-`, or `ConvertTo-` cmdlets. For example, here's how you could produce a custom table from the `Win32_BIOS` class:

```
PS C:\> Gwmi Win32_BIOS | Format-Table SerialNumber,Version -auto
```

In chapter 10, we showed you a technique that uses the `Format-Table` cmdlet to produce custom columns. That technique can come in handy when you wish to query a

couple of WMI classes from a given computer and aggregate the results into a single table. To do so, you create a custom column for the table and have that column's expression execute a whole new WMI query. The syntax for the command can be confusing, but the results are impressive:

```
PS C:\> gwmi -class win32_bios -computer server-r2,localhost |  
  format-table @{label='ComputerName';expression={$_.__SERVER}},  
  @{label='BIOSSerial';expression={$_.SerialNumber}},  
  @{label='OSBuild';expression= {gwmi -class \win32_operatingsystem  
    -computer $_.__SERVER | select-object -expand BuildNumber}} -autosize  
  
ComputerName BIOSSerial OSBuild  
-----  
SERVER-R2 VMware-56 4d 45 fc 13 92 de c3-93 5c 40 6b 47 bb 5b 86 7600
```

The preceding syntax can be a bit easier to parse if you copy it into the PowerShell ISE and format it a bit:

```
gwmi -class win32_bios -computer server-r2,localhost |  
format-table @{label='ComputerName';expression={$_.__SERVER}},  
@{label='BIOSSerial';expression={$_.SerialNumber}},  
@{label='OSBuild';expression={  
    gwmi -class win32_operatingsystem -comp $_.__SERVER |  
    select-object -expand BuildNumber}  
} -autosize
```

Here's what's happening:

- `Get-WmiObject` is querying `Win32_BIOS` from two computers.
- The results are being piped to `Format-Table`. `Format-Table` is being told to create three custom columns:
 - The first column is named `ComputerName`, and it's using the `__SERVER` system property from the `Win32_BIOS` instance.
 - The second column is named `BIOSSerial`, and it's using the `SerialNumber` property of the `Win32_BIOS` instance.
 - The third column is named `OSBuild`. This column is executing a whole new `Get-WmiObject` query, retrieving the `Win32_OperatingSystem` class from the `__SERVER` system property of the `Win32_BIOS` instance (of the same computer). That result is being piped to `Select-Object`, which is selecting the contents of the `BuildNumber` property of the `Win32_OperatingSystem` instance and using that as the value for the `OSBuild` column.

That syntax is complex, but it offers powerful results. It's also a great example of how much you can achieve by stringing together a few carefully selected PowerShell cmdlets.

As we've mentioned, some WMI classes include methods. You'll see how to use those in chapter 16; doing so can be complicated, and the topic deserves its own chapter.

14.6 Using Get-CimInstance

`Get-CimInstance` was new in PowerShell v3, and it works a lot like `Get-WmiObject` but with a few major syntactical differences:

- You use `-ClassName` instead of `-Class` (although you have to type only `-Class`, so if that's all you remember, it's fine).
- There's no `-List` parameter to list all the classes in a namespace. Instead, run `Get-CimClass` and use the `-Namespace` parameter to list classes.
- There's no `-Credential` parameter; if you intend to query from a remote computer and need to provide alternative credentials, send `Get-CimInstance` via `Invoke-Command` (which you learned in the previous chapter).

For example

```
PS C:\> Get-CimInstance -ClassName Win32_LogicalDisk
```

DeviceID	DriveType	ProviderName	VolumeName	Size	FreeSpace
A:	2				
C:	3			687173...	580806...
D:	5		HB1_CCBA_X64F...	358370...	0

If you want to query a remote computer by using alternate credentials, you can use a command like this:

```
invoke-command -ScriptBlock { Get-CimInstance -ClassName win32_process }
    ↗ -ComputerName WIN8 -Credential DOMAIN\Administrator
```

14.7 WMI documentation

We mentioned earlier that a search engine is often the best way to find whatever WMI documentation exists. The `Win32_` classes are well documented in Microsoft's MSDN Library site, but a search engine remains the easiest way to land on the right page. Enter the name of the class in Google or Bing, and the first hit will usually be a page on <http://msdn.microsoft.com>.

14.8 Common points of confusion

Because we've spent the last 10 chapters telling you to use the built-in PowerShell help, you might be inclined to run something like `help win32_service` right inside PowerShell. Sadly, that won't work. The operating system itself doesn't contain any WMI documentation, so PowerShell's help function wouldn't have any place to go look for it. You're stuck with whatever help you can find online—and much of that will be from other administrators and programmers, not from Microsoft. Search for `root\SecurityCenter`, for example, and you won't find a single Microsoft documentation page in the results, which is unfortunate.

The different filter criteria that WMI uses are also common points of confusion. You should always provide a filter whenever you need anything other than all of the available instances, but you'll have to memorize that different filter syntax. The filter

syntax is passed along to WMI and not processed by PowerShell, which is why you have to use the syntax that WMI prefers, instead of the native PowerShell operators.

Part of what makes WMI confusing for some of our classroom students is that, although PowerShell provides an easy way to query information from WMI, WMI isn't integrated into PowerShell. WMI is an external technology, and it has its own rules and its own way of working. Although you can get to it from within PowerShell, it won't behave exactly like other cmdlets and techniques that are integrated completely within PowerShell. Keep that in mind, and watch for little points of confusion that result from WMI's individuality.

14.9 Lab

NOTE For this lab, you need any Windows computer running PowerShell v3 or later.

Take some time to complete the following hands-on tasks. Much of the difficulty in using WMI is in finding the class that will give you the information you need, so much of your time in this lab will be spent tracking down the right class. Try to think in keywords (we'll provide some hints), and use a WMI explorer to quickly search through classes (the WMI Explorer we use lists classes alphabetically, making it easier for us to validate our guesses). Keep in mind that PowerShell's help system can't help you find WMI classes.

- 1 What class can you use to view the current IP address of a network adapter? Does the class have any methods that you could use to release a DHCP lease? (Hint: *network* is a good keyword here.)
- 2 Create a table that shows a computer name, operating system build number, operating system description (caption), and BIOS serial number. (Hint: you've seen this technique, but you need to reverse it to query the OS class first, and then query the BIOS second.)
- 3 Query a list of hotfixes using WMI. (Hint: Microsoft formally refers to these as *quick-fix engineering*.) Is the list different from that returned by the Get-Hotfix cmdlet?
- 4 Display a list of services, including their current statuses, their start modes, and the accounts they use to log on.
- 5 Using the CIM cmdlets, list all available classes in the SecurityCenter2 namespace with Product as part of the name.
- 6 Once you discover the name, use the CIM cmdlets to display any antispyware application. You can also check for antivirus products.

TRY IT NOW After you've completed this lab, try completing review lab 2, which you'll find in the appendix.

14.10 Further exploration

WMI is a vast, complex technology, and someone could easily write an entire book about it. In fact, someone did: *PowerShell and WMI* by fellow MVP Richard Siddaway (Manning, 2012). The book provides tons of examples and discusses some of the new capabilities of the CIM cmdlets introduced in PowerShell v3. We heartily recommend this book to anyone interested in learning more about WMI.

If you've found WMI to be thoroughly confusing or frustrating, don't worry. That's a common reaction. But we have some good news: In PowerShell v3 and later, you can often use WMI without seeming to "touch" WMI. That's because Microsoft has written hundreds of cmdlets that "wrap around" WMI. These cmdlets provide help, discoverability, examples, and all the good things cmdlets give you, but they use WMI internally. This makes it easier to take advantage of the power of WMI without having to deal with its frustrating elements.

14.11 Lab answers

- 1 You can use the `Win32_NetworkAdapterConfiguration` class.

If you run `Get-WmiObject` for this class and pipe to `Get-Member`, you should see numerous DHCP-related methods. You can also find this by using a CIM cmdlet:

```
Get-CimClass win32_networkadapterconfiguration | select -expand methods | where Name -match "dhcp"
```

- 2 `get-wmiobject win32_operatingsystem | Select BuildNumber,Caption, @{l='Computername';e={$_.__SERVER}}, @{l='BIOSSerialNumber';e={(gwmi win32_bios).serialnumber }} } | ft -auto`

or by using the CIM cmdlets:

```
get-ciminstance win32_operatingsystem | Select BuildNumber,Caption, @{l='Computername';e={$_.CSName}}, @{l='BIOSSerialNumber';e={(get-ciminstance win32_bios).serialnumber }} } | ft -auto
```

- 3 `get-wmiobject win32_quickfixengineering`

- 4 You should see that the results are similar.

- 5 `get-wmiobject win32_service | Select Name,State,StartMode, StartName`

or

```
get-ciminstance win32_service | Select Name,State,StartMode, StartName
```

- 6 `get-cimclass -namespace root/SecurityCenter2 -ClassName *product`
`get-ciminstance -namespace root/SecurityCenter2 -ClassName AntiSpywareProduct`

15

Multitasking with background jobs

Everyone's always telling you to *multitask*, right? Why shouldn't PowerShell help you with that by doing more than one thing at a time? It turns out that PowerShell can do exactly that, particularly for longer-running tasks that might involve multiple target computers. Make sure you've read chapters 13 and 14 before you dive into this chapter, because we'll be taking those remoting and WMI concepts a step further.

15.1 **Making PowerShell do multiple things at the same time**

You should think of PowerShell as a single-threaded application, meaning that it can do only one thing at once. You type a command, you hit Enter, and the shell waits for that command to execute. You can't run a second command until the first command finishes.

But with its background jobs functionality, PowerShell has the ability to move a command onto a separate background thread (a separate, background PowerShell process). That enables the command to run in the background, as you continue to use the shell for another task. But you have to make that decision before running the command; after you press Enter, you can't decide to move a long-running command into the background.

After commands are in the background, PowerShell provides mechanisms to check on their status, retrieve any results, and so forth.

NOTE The early releases of PowerShell for Linux have some of the pieces for using PowerShell background jobs but they aren't fully baked. We expect that PowerShell on Linux will eventually support PowerShell background jobs but we can't guarantee it will behave 100% as its Windows counterpart. But you know how to read PowerShell help, and this chapter explains the concepts.

15.2 Synchronous vs. asynchronous

Let's get some terminology out of the way first. PowerShell runs normal commands *synchronously*, meaning you hit Enter and then wait for the command to complete. Moving a job into the background allows it to run *asynchronously*, meaning you can continue to use the shell for other tasks as the command completes.

Let's look at some important differences between running commands in these two ways:

- When you run a command synchronously, you can respond to input requests. When you run commands in the background, there's no opportunity to see input requests—in fact, they'll stop the command from running.
- Synchronous commands produce error messages when something goes wrong. Background commands produce errors, but you won't see them immediately. You'll have to make arrangements to capture them, if necessary. (Chapter 22 discusses how you do that.)
- If you omit a required parameter on a synchronous command, PowerShell can prompt you for the missing information. On a background command, it can't, so the command will fail.
- The results of a synchronous command start displaying as soon as they become available. With a background command, you wait until the command finishes running and then retrieve the cached results.

We typically run commands synchronously to test them out and get them working properly, and run them in the background only after we know they're fully debugged and working as we expect. We follow these measures to ensure that the command will run without problems, and that it will have the best chance of completing in the background.

PowerShell refers to background commands as *jobs*. You can create jobs in several ways, and you can use several commands to manage them.

Above and beyond

Technically, the jobs we discuss in this chapter are just one kind of job you'll encounter. Jobs are an extension point for PowerShell, meaning it's possible for someone (either in Microsoft or as a third party) to create other things called jobs that look and work a bit differently than what we describe in this chapter. In fact, scheduled jobs, covered later in this chapter, work differently than the "normal" jobs that we cover first, and you may run into other kinds of jobs as you extend the shell for various purposes. We want you to understand that little detail, and to know that what you're learning applies only to the native, regular jobs that come with PowerShell.

15.3 Creating a local job

The first type of job we cover is perhaps the easiest: a local job. This is a command that runs more or less entirely on your local computer (with exceptions that we cover in a second) and that runs in the background.

To launch one of these jobs, you use the `Start-Job` command. A `-scriptblock` parameter lets you specify the command (or commands) to run. PowerShell makes up a default job name (`Job1`, `Job2`, and so on), or you can specify a custom job name by using the `-Name` parameter. If you need the job to run under alternative credentials, a `-credential` parameter will accept a `DOMAIN\Username` credential and prompt you for the password. Rather than specifying a script block, you can specify the `-FilePath` parameter to have the job execute an entire script file full of commands.

Here's a simple example:

```
PS C:\> start-job -scriptblock { dir }
```

Id	Name	State	HasMoreData	Location
--	---	-----	-----	-----
1	Job1	Running	True	localhost

The command creates the job object, and as the previous example shows, the job begins running immediately. The job is also assigned a sequential job ID number, which is shown in the table.

We said these jobs run entirely on your local computer, and that's true. But the commands in the job are allowed to access remote computers if you run a command that supports a `-computerName` parameter. Here's an example:

```
PS C:\> start-job -scriptblock {
  ↪get-eventlog security -computer server-r2
  ↪}
```

Id	Name	State	HasMoreData	Location
--	---	-----	-----	-----
3	Job3	Running	True	localhost

TRY IT NOW We hope you'll follow along and run all of these commands. If you have only a single computer to work with, refer to its computer name and use `localhost` as an alternative, so that PowerShell will act like it's dealing with two computers.

The processing for this job happens on your local computer. It contacts the specified remote computer (SERVER-R2 in this example), so the job is, in a way, a “remote job.” But because the command itself is running locally, we still refer to this as a local job.

Sharp-eyed readers will note that the first job we created is named `Job1` and given the ID 1, but the second job is `Job3` with ID 3. It turns out that every job has at least one *child job*, and the first child job (a child of `Job1`) is given the name `Job2` and the ID 2. We'll get to child jobs later in this chapter.

Here's something to keep in mind: Although local jobs run locally, they do require the infrastructure of PowerShell's remoting system, which we covered in chapter 13. If you haven't enabled remoting, you won't be able to start local jobs.

15.4 WMI, as a job

Another way to start a job is to use `Get-WmiObject`. As we explained in the previous chapter, the `Get-WmiObject` command can contact one or more remote computers, but it does so sequentially. That means a long list of computer names can cause the command to take a long time to process, so that command is a natural choice for moving to a background job. To do so, you use `Get-WmiObject` as usual but add the `-AsJob` parameter. You don't get to specify a custom job name at this point; you're stuck with the default job name that PowerShell applies.

TRY IT NOW If you're running the same commands on your test system, you'll need to create a text file called `allservers.txt`. We put it in the root of our C: drive (because that's where we have PowerShell focused for these examples), and we put several computer names in the file, listing one name per line. You can list your computer name and `localhost` to duplicate the results we're showing you.

```
PS C:\> get-wmiobject win32_operatingsystem -computername
➥ (get-content allservers.txt) -asjob

WARNING: column "Command" does not fit into the display and was removed.
Id          Name        State      HasMoreData     Location
--          ----        -----      -----          -----
5           Job5       Running    False         server-r2,lo...
```

This time, the shell creates one top-level parent job (Job5, which is shown in the output of the command), and it creates one child job for each computer that you specify. You can see that the `Location` column in the output table lists as many of the computer names as will fit, indicating that the job will be running against those computers.

It's important to understand that `Get-WmiObject` executes only on your computer; the cmdlet uses normal WMI communications to contact the remote computers you specify. It still does this one at a time and follows the usual defaults of skipping computers that aren't available, and so forth. In fact, it works identically to using `Get-WmiObject` synchronously, except that the cmdlet runs in the background.

TRY IT NOW You have commands other than `Get-WmiObject` that can start a job. Try running `Help * -parameter asjob` to see if you can find all of them.

Note that the newer `Get-CimInstance` command, which you learned about in chapter 14, doesn't have an `-AsJob` parameter. If you want to use it in a job, run either `Start-Job` or `Invoke-Command` (which you'll learn about next), and include `Get-CimInstance` (or for that matter, any of the new CIM commands) in the script block.

15.5 Remoting, as a job

Let's review the final technique you can use to create a new job: PowerShell's remoting capabilities, which you learned about in chapter 13. As with `Get-WmiObject`, you start this kind of job by adding an `-AsJob` parameter, but this time you add it to the `Invoke-Command` cmdlet.

There's an important difference here: Whatever command you specify in the `-ScriptBlock` (or `-Command`, which is an alias for the same parameter) will be transmitted in parallel to each computer you specify. Up to 32 computers can be contacted at once (unless you modify the `-ThrottleLimit` parameter to allow more or fewer), so if you specify more than 32 computer names, only the first 32 will start. The rest will start after the first set begins to finish, and the top-level job will show a completed status after all of the computers finish.

Unlike the other two ways to start a job, this technique requires you to have PowerShell v2 or v3 installed on each target computer, and remoting to be enabled in PowerShell on each target computer. Because the command physically executes on each remote computer, you're distributing the computing workload, which can help improve performance for complex or long-running commands. The results come back to your computer and are stored with the job until you're ready to review them.

In the following example, you'll also see the `-JobName` parameter that lets you specify a job name other than the boring default:

```
PS C:\> invoke-command -command { get-process }
  ↪-computername (get-content .\allservers.txt )
  ↪-asjob -jobname MyRemoteJob

WARNING: column "Command" does not fit into the display and was removed.
Id          Name          State      HasMoreData      Location
--          ----          -----      -----          -----
8          MyRemoteJob    Running    True           server-r2,lo...
```

15.6 Getting job results

The first thing you'll probably want to do after starting a job is to check whether your jobs have finished. The `Get-Job` cmdlet retrieves every job currently defined by the system and shows you each one's status:

```
PS C:\> get-job

Id          Name          State      HasMoreData      Location
--          ----          -----      -----          -----
1          Job1          Completed  True           localhost
3          Job3          Completed  True           localhost
5          Job5          Completed  True           server-r2,lo...
8          MyRemoteJob   Completed  True           server-r2,lo...
```

You can also retrieve a specific job by using its ID or its name. We suggest that you do that and pipe the results to `Format-List *`, because you've gathered some valuable information:

```
PS C:\> get-job -id 1 | format-list *
```

State	:	Completed
HasMoreData	:	True
StatusMessage	:	
Location	:	localhost
Command	:	dir
JobStateInfo	:	Completed
Finished	:	System.Threading.ManualResetEvent
InstanceId	:	e1ddde9e-81e7-4b18-93c4-4c1d2a5c372c
Id	:	1
Name	:	Job1
ChildJobs	:	{Job2}
Output	:	{}
Error	:	{}
Progress	:	{}
Verbose	:	{}
Debug	:	{}
Warning	:	{}

TRY IT NOW If you’re following along, keep in mind that your job IDs and names might be different from ours. Focus on the output of Get-Job to retrieve your job IDs and names, and substitute yours in the examples. Also keep in mind that Microsoft has expanded the job object over the last few PowerShell versions, so your output when looking at all properties might be different.

The ChildJobs property is one of the most important pieces of information, and we’ll cover it in a moment.

To retrieve the results from a job, use Receive-Job. But before you run this, you need to know a few things:

- You have to specify the job from which you want to receive results. You can do this by job ID or job name, or by getting jobs with Get-Job and piping them to Receive-Job.
- If you receive the results of the parent job, those results will include all output from all child jobs. Alternatively, you can choose to get the results from one or more child jobs.
- Typically, receiving the results from a job clears them out of the job output cache, so you can’t get them a second time. Specify -keep to keep a copy of the results in memory. Or you can output the results to CliXML, if you want to retain a copy to work with.
- The job results may be deserialized objects, which you learned about in chapter 13. These are snapshots from the point in time when they were generated, and they may not have any methods that you can execute. But you can pipe the job results directly to cmdlets such as Sort-Object, -Format-List, Export-CSV, ConvertTo-HTML, Out-File, and so on, if desired.

Here's an example:

```
PS C:\> receive-job -id 1

Directory: C:\Users\Administrator\Documents
Mode                LastWriteTime     Length Name
----                -----          ----- 
d----       11/21/2015  11:53 AM           Integration Services Script Component
d----       11/21/2015  11:53 AM           Integration Services Script Task
d----       4/23/2010   7:54 AM            SQL Server Management Studio
d----       4/23/2010   7:55 AM            Visual Studio 2005
d----       11/21/2009  11:50 AM            Visual Studio 2008
```

The preceding output shows an interesting set of results. Here's a quick reminder of the command that launched this job in the first place:

```
PS C:\> start-job -scriptblock { dir }
```

Although our shell was in the C: drive when we ran this, the directory in the results is C:\Users\Administrator\Documents. As you can see, even local jobs take on a slightly different context when they run, which may result in a change of location. Don't ever make assumptions about file paths from within a background job: Use absolute paths to make sure you can refer to whatever files your job command may require. If we wanted the background job to get a directory of C:, we should have run the following command:

```
PS C:\> start-job -scriptblock { dir c:\ }
```

When we received the results from job 1, we didn't specify -keep. If we try to get those same results again, we'll get nothing, because the results are no longer cached with the job:

```
PS C:\> receive-job -id 1
```

Here's how to force the results to stay cached in memory:

```
PS C:\> receive-job -id 3 -keep
```

Index	Time	EntryType	Source	InstanceID	Message
6542	Oct 04 11:55	SuccessA...	Microsoft-Windows...	4634	An...
6541	Oct 04 11:55	SuccessA...	Microsoft-Windows...	4624	An...
6540	Oct 04 11:55	SuccessA...	Microsoft-Windows...	4672	Sp...
6539	Oct 04 11:54	SuccessA...	Microsoft-Windows...	4634	An...

You'll eventually want to free up the memory that's being used to cache the job results, and we'll cover that in a bit. But first, let's look at a quick example of piping the job results directly to another cmdlet:

```
PS C:\> receive-job -name myremotejob | sort-object PSComputerName |
  ↪Format-Table -groupby PSComputerName
```

```
PSComputerName: localhost
```

Handles	NPM (K)	PM (K)	WS (K)	VM (M)	CPU (s)	Id	ProcessName	PSComputerName
195	10	2780	5692	30	0.70	484	lsm	localhost
237	38	40704	36920	547	3.17	1244	Micro...	localhost
146	17	3260	7192	60	0.20	3492	msdtc	localhost
1318	100	42004	28896	154	15.31	476	lsass	localhost

This was the job we started by using `Invoke-Command`. As always, the cmdlet has added the `PSComputerName` property so we can keep track of which object came from which computer. Because we retrieved the results from the top-level job, this includes all of the computers we specified, which allows this command to sort them on the computer name and then create an individual table group for each computer.

`Get-Job` can also keep you informed about which jobs have results remaining:

```
PS C:\> get-job

WARNING: column "Command" does not fit into the display and was removed.
Id          Name          State      HasMoreData      Location
--          --          -----      -----          -----
1           Job1         Completed   False          localhost
3           Job3         Completed   True           localhost
5           Job5         Completed   True           server-r2,lo...
8           MyRemoteJob  Completed   False          server-r2,lo...
```

The `HasMoreData` column will be `False` when no output is cached with that job. In the case of `Job1` and `MyRemoteJob`, we've already received those results and didn't specify `-keep` at that time.

15.7 Working with child jobs

We mentioned earlier that all jobs consist of one top-level parent job and at least one child job. Let's look at a job again:

```
PS C:\> get-job -id 1 | format-list *

State          : Completed
HasMoreData    : True
StatusMessage  :
Location       : localhost
Command        : dir
JobStateInfo   : Completed
Finished       : System.Threading.ManualResetEvent
InstanceId     : e1ddde9e-81e7-4b18-93c4-4c1d2a5c372c
Id             : 1
Name           : Job1
ChildJobs      : {Job2}
Output          : {}
Error          : {}
Progress        : {}
```

```
Verbose      : {}
Debug       : {}
Warning     : {}
```

TRY IT NOW Don't follow along for this part, because if you've been following along up to now, you've already received the results of Job1. If you'd like to try this, start a new job by running `Start-Job -script { Get-Service }`, and use that new job's ID instead of the ID number 1 we used in our example.

You can see that Job1 has a child job, Job2. You can get it directly now that you know its name:

```
PS C:\> get-job -name job2 | format-list *

State          : Completed
StatusMessage  :
HasMoreData    : True
Location       : localhost
Runspace       : System.Management.Automation.RemoteRunspace
Command        : dir
JobStateInfo   : Completed
Finished       : System.Threading.ManualResetEvent
InstanceId     : a21a91e7-549b-4be6-979d-2a896683313c
Id             : 2
Name           : Job2
ChildJobs      : {}
Output         : {Integration Services Script Component, Integration Services Script Task, SQL Server Management Studio, Visual Studio 2005...}
Error          : {}
Progress       : {}
Verbose        : {}
Debug          : {}
Warning        : {}
```

Sometimes a job has too many child jobs to list in that form, so you may want to list them a bit differently, as follows:

```
PS C:\> get-job -id 1 | select-object -expand childjobs
WARNING: column "Command" does not fit into the display and was removed.
Id          Name          State      HasMoreData      Location
--          ---          -----      -----          -----
2          Job2          Completed  True            localhost
```

This technique creates a table of the child jobs for job ID 1, and the table can be whatever length it needs to be to list them all.

You can receive the results from any individual child job by specifying its name or ID with `Receive-Job`.

15.8 Commands for managing jobs

Jobs also use three more commands. For each of these, you can specify a job either by giving its ID, giving its name, or by getting the job and piping it to one of these cmdlets:

- `Remove-Job`—This deletes a job, and any output still cached with it, from memory.
- `Stop-Job`—If a job seems to be stuck, this command terminates it. You can still receive whatever results were generated to that point.
- `Wait-Job`—This is useful if a script is going to start a job and you want the script to continue only when the job is done. This command forces the shell to stop and wait until the job is completed, and then allows the shell to continue.

For example, to remove the jobs that we've already received output from, we'd use the following command:

```
PS C:\> get-job | where { -not $_.HasMoreData } | remove-job
PS C:\> get-job

WARNING: column "Command" does not fit into the display and was removed.
Id          Name        State      HasMoreData    Location
--          ---        -----      -----        -----
3           Job3       Completed   True         localhost
5           Job5       Completed   True         server-r2,lo...
```

Jobs can also fail, meaning that something went wrong with their execution. Consider this example:

```
PS C:\> invoke-command -command { nothing } -computer notonline -asjob
➥ -jobname ThisWillFail

WARNING: column "Command" does not fit into the display and was removed.
Id          Name        State      HasMoreData    Location
--          ---        -----      -----        -----
11          ThisWillFail Failed     False        notonline
```

Here, we started a job with a bogus command and targeted a nonexistent computer. The job immediately failed, as shown in its status. We don't need to use `Stop-Job` at this point; the job isn't running. But we can get a list of its child jobs:

```
PS C:\> get-job -id 11 | format-list *

State          : Failed
HasMoreData    : False
StatusMessage  :
Location       : notonline
Command        : nothing
JobStateInfo   : Failed
Finished       : System.Threading.ManualResetEvent
InstanceId     : d5f47bf7-53db-458d-8a08-07969305820e
Id             : 11
Name           : ThisWillFail
ChildJobs      : {Job12}
Output          :
Error          :
```

```
Progress      : {}
Verbose       : {}
Debug         : {}
Warning        : {}
```

And we can then get that child job:

```
PS C:\> get-job -name job12
WARNING: column "Command" does not fit into the display and was removed.
Id          Name        State     HasMoreData   Location
--          ----        -----    -----        -----
12          Job12      Failed    False        notonline
```

As you can see, no output was created for this job, so you won't have any results to retrieve. But the job's errors are stored in the results, and you can get them by using Receive-Job:

```
PS C:\> receive-job -name job12
Receive-Job : [notonline] Connecting to remote server failed with the following error message : WinRM cannot process the request. The following error occurred while using Kerberos authentication: The network path was not found.
```

The full error is much longer; we truncated it here to save space. You'll notice that the error includes the computer name that the error came from, [notonline]. What happens if only one of the computers can't be reached? Let's try:

```
PS C:\> invoke-command -command { nothing }
➥-computer notonline,server-r2 -asjob -jobname ThisWillFail
WARNING: column "Command" does not fit into the display and was removed.
Id          Name        State     HasMoreData   Location
--          ----        -----    -----        -----
13          ThisWillFail  Running   True        notonline,se...
```

After waiting for a bit, we run the following:

```
PS C:\> get-job
WARNING: column "Command" does not fit into the display and was removed.
Id          Name        State     HasMoreData   Location
--          ----        -----    -----        -----
13          ThisWillFail  Failed    False        notonline,se...
```

The job still fails, but let's look at the individual child jobs:

```
PS C:\> get-job -id 13 | select -expand childjobs
WARNING: column "Command" does not fit into the display and was removed.
Id          Name        State     HasMoreData   Location
--          ----        -----    -----        -----
14          Job14      Failed    False        notonline
15          Job15      Failed    False        server-r2
```

OK, they both fail. We have a feeling we know why Job14 doesn't work, but what's wrong with Job15?

```
PS C:\> receive-job -name job15
Receive-Job : The term 'nothing' is not recognized as the name of a cmdlet
, function, script file, or operable program. Check the spelling of the na
me, or if a path was included, verify that the path is correct and try aga
in.
```

Ah, that's right, we told it to run a bogus command. As you can see, each child job can fail for different reasons, and PowerShell tracks each one individually.

15.9 Scheduled jobs

PowerShell v3 introduced support for scheduled jobs—a PowerShell-friendly way of creating tasks in the Windows Task Scheduler. These jobs work differently from the jobs we've discussed up to this point; as we wrote earlier, jobs are an extension point in PowerShell, meaning there can be many kinds of job that work slightly differently. The scheduled jobs feature is one of those different kinds of job. These are also slightly different from standard Task Scheduler jobs, in that the output from these jobs is specifically stored on disk for PowerShell to retrieve later. In fact, the term *scheduled jobs* is specifically different from *scheduled tasks*—with the former being the PowerShell-specific thing, and the latter being the same old tasks you've always used.

You start a scheduled job by creating a trigger (`New-JobTrigger`) that defines when the task will run. You can also set options for the job (`New-ScheduledTaskOption`). Then you register the job (`Register-ScheduledJob`) with Task Scheduler. This creates the job definition in Task Scheduler's XML format, on disk, and creates a folder hierarchy to contain the results of the job each time it runs.

Let's look at an example:

```
PS C:\> Register-ScheduledJob -Name DailyProcList -ScriptBlock {
    Get-Process } -Trigger (New-JobTrigger -Daily -At 2am)
    -ScheduledJobOption (New-ScheduledJobOption -WakeToRun -RunElevated)

WARNING: column "Enabled" does not fit into the display and was removed.
Id      Name          JobTriggers      Command
--      --          -----          -----
1      DailyProcList {1}           Get-Process
```

This creates a new job that runs `Get-Process` every day at 2 a.m., waking the computer if necessary, and running under elevated privileges. After the job runs, you can come back into PowerShell and run `Get-Job` to see a standard job for each time the scheduled task completed:

```
PS C:\> get-job

WARNING: column "Command" does not fit into the display and was removed.
Id      Name          State        HasMoreData      Location
--      --          -----        -----          -----
6      DailyProcList  Completed    True            localhost
9      DailyProcList  Completed    True            localhost
```

Unlike normal jobs, receiving the results from scheduled jobs doesn't delete the results, because they're cached on disk and not in memory. You can continue to

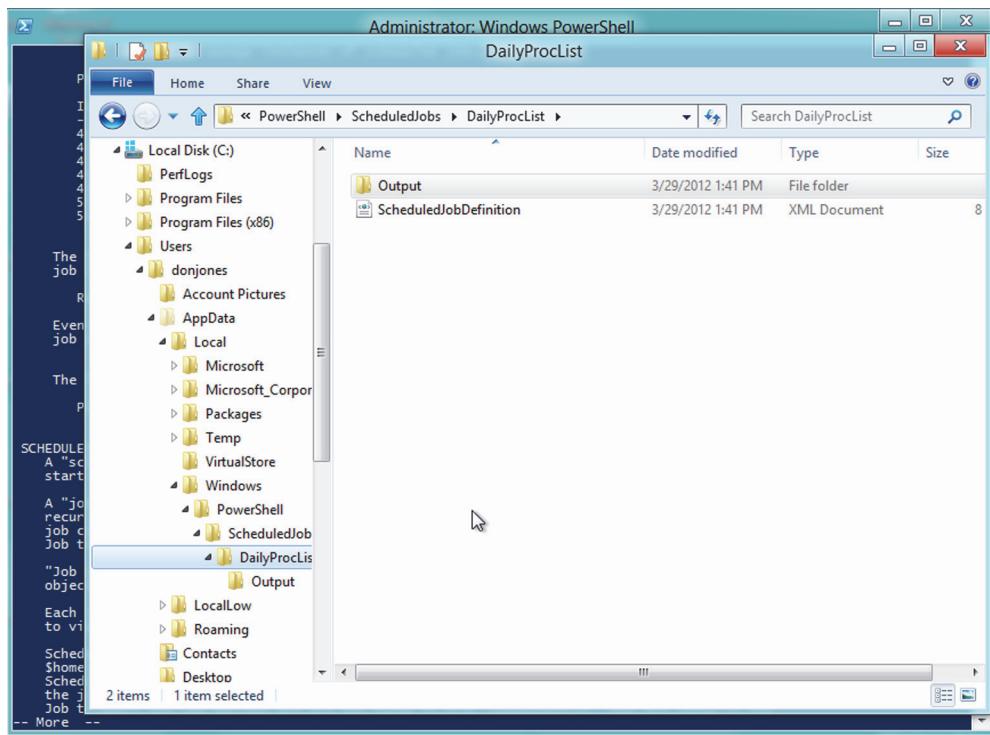

Figure 15.1 Scheduled job output is stored on disk.

receive the results over and over. When you remove the job, the results are removed from disk too. As shown in figure 15.1, this output resides in a specific folder on disk, and `Receive-Job` is capable of reading those files.

You can control the number of stored result sets by using the `-MaxResultCount` parameter of `Register-ScheduledJob`.

15.10 Common points of confusion

Jobs are usually straightforward, but we've seen folks do one thing that causes confusion. Don't do this:

```
PS C:\> invoke-command -command { Start-Job -scriptblock { dir } }
➥-computername Server-R2
```

Doing so starts up a temporary connection to SERVER-R2 and starts a local job. Unfortunately, that connection immediately terminates, so you have no way to reconnect and retrieve that job. In general, then, don't mix and match the three ways of starting jobs.

The following is also a bad idea:

```
PS C:\> start-job -scriptblock { invoke-command -command { dir }
➥-computername SERVER-R2 }
```

That's completely redundant; keep the `Invoke-Command` section and use the `-AsJob` parameter to have it run in the background.

Less confusing, but equally interesting, are the questions our classroom students often ask about jobs. Probably the most important of these is, "Can we see jobs started by someone else?" The answer is no, except for scheduled jobs. Normal jobs are contained entirely within the PowerShell process, and although you can see that another user is running PowerShell, you can't see inside that process. It's like any other application: You can see that another user is running Microsoft Word, for example, but you can't see what documents that user is editing, because those documents exist entirely inside of Word's process.

Jobs last only as long as your PowerShell session is open. After you close it, any jobs defined within it disappear. Jobs aren't defined anywhere outside PowerShell, so they depend upon its process continuing to run in order to maintain themselves.

Scheduled jobs are the exception to the previous statement: Anyone with permission can see them, modify them, delete them, and retrieve their results, because they're stored on disk. Note that they're stored under your user profile, so it typically requires an administrator to get the files (and results) out of your profile.

15.11 Lab

NOTE For this lab, you need a Windows 8 or Windows Server 2012, or later, computer running PowerShell v3 or later.

The following exercises should help you understand how to work with various types of jobs and tasks in PowerShell. As you work through these exercises, don't feel you have to write a one-line solution. Sometimes it's easier to break things down into separate steps.

- 1 Create a one-time background job to find all the PowerShell scripts on the C: drive. Any task that might take a long time to complete is a great candidate for a job.
- 2 You realize it would be helpful to identify all PowerShell scripts on some of your servers. How would you run the same command from task 1 on a group of remote computers?
- 3 Create a background job that will get the latest 25 errors from the system event log on your computer and export them to a CliXML file. You want this job to run every day, Monday through Friday, at 6 a.m., in order for it to be ready for you to look at when you come in to work.
- 4 What cmdlet would you use to get the results of a job, and how would you save the results in the job queue?

15.12 Lab answers

```
1 Start-Job {dir c:\ -recurse -filter '*.ps1'}
```

```
2 Invoke-Command -scriptblock {dir c:\ -recurse -filter *.ps1}
   -computername (get-content computers.txt) -asjob
```

```
3 $Trigger=New-JobTrigger -At "6:00AM" -DaysOfWeek "Monday",
   "Tuesday", "Wednesday", "Thursday", "Friday" -Weekly
$Command={ Get-EventLog -LogName System -Newest 25 -EntryType Error
| Export-Clixml c:\work\25SysErr.xml}
```

```
Register-ScheduledJob -Name "Get 25 System Errors" -ScriptBlock
$Command -Trigger $Trigger
```

```
#check on what was created
Get-ScheduledJob | Select *
```

```
4 Receive-Job -id 1 -keep
```

Of course, you would use whatever job ID was applicable or the job name.

Working with many objects, one at a time

The whole point of PowerShell is to automate administration, and that often means you'll want to perform some tasks with multiple targets. You might want to reboot several computers, reconfigure several services, modify several mailboxes, and so on. In this chapter, you'll learn three distinct techniques for accomplishing these and other multiple-target tasks: batch cmdlets, WMI (and other object) methods, and object enumeration. Also, you should know that most of the examples in this chapter won't work on Linux or macOS; they're (at least currently) Windows-only. But the *concepts* and *techniques* here are the same regardless of the OS you're using.

16.1 Automation for mass management

We know this isn't a book about VBScript, but we want to use a VBScript example to briefly illustrate the way that multiple-target administration—what Don likes to call *mass management*—has been approached in the past. Consider this example (you don't need to type this in and run it—we're going to discuss the approach, not the results):

```
For Each varService in colServices
    varService.ChangeStartMode("Automatic")
Next
```

This kind of approach is common not only in VBScript but also throughout the world of programming. The following steps illustrate what it does:

- 1 Assumes that the variable `colServices` contains multiple services. It doesn’t matter how they got in there, because you could retrieve the services in many ways. What matters is that you’ve already retrieved the services and put them into this variable.
- 2 The `ForEach` construct goes through, or *enumerates*, the services one at a time. As it does this, it places each service into the variable `varService`. Within the construct then, `varService` contains only a single service. If `colServices` contains 50 services, the construct’s contents would execute 50 times, and each time `varService` would contain a different one of the 50 services.
- 3 Within the construct, a method is executed each time—in this example, `-ChangeStartMode()`—to perform a task.

If you think about it carefully, you’ll realize that this code isn’t doing something to a bunch of services at once. Instead, it’s doing something to one service at a time, exactly as you would if you were manually reconfiguring the services by using the graphical user interface. The only difference is that this code makes the computer go through the services one at a time.

Computers are good at repeating things over and over, so this isn’t a horrible approach. The problem is that this approach requires us to give the computer a longer and fairly complicated set of instructions. Learning the language necessary to give that set of instructions can take time, which is why a lot of administrators try to avoid VBScript and other scripting languages.

PowerShell can duplicate this approach, and we’ll show you how later in this chapter, because sometimes you have to resort to this method. But the approach of having the computer enumerate objects isn’t the most efficient way to use PowerShell. In fact, PowerShell offers two other techniques that are easier to learn and easier to type, and they’re often more powerful.

16.2 The preferred way: “batch” cmdlets

As you’ve learned in several previous chapters, many PowerShell cmdlets can accept batches, or *collections*, of objects to work with. In chapter 6, for example, you learned that objects can be piped from one cmdlet to another, like this (please don’t run this—it could crash your computer):

```
Get-Service | Stop-Service
```

This is an example of batch administration using a cmdlet. In this case, `Stop-Service` is specifically designed to accept one service object, or many service objects, from the pipeline, and then stop them. `Set-Service`, `Stop-Process`, `Move-ADObject`, and `Move-Mailbox` are all examples of cmdlets that accept one or more input objects and then perform a task or action with each of them. You don’t need to manually enumerate the objects by using a construct, as we did in the VBScript example in the previous section. PowerShell knows how to work with batches of objects and can handle them for you with a less complex syntax.

These so-called *batch cmdlets* (that's our name for them—it's not an official term) are our preferred way of performing mass management. For example, let's suppose we need to change the start mode of three services. Rather than using an approach like the VBScript one, we could do this:

```
Get-Service -name BITS,Spooler,W32Time | Set-Service -startuptype Automatic
```

In a way, Get-Service is also a kind of batch cmdlet, because it's capable of retrieving services from multiple computers. Suppose you need to change those same three services across a set of three computers:

```
Get-Service -name BITS,Spooler,W32Time -computer Server1,Server2,Server3 |  
  Set-Service -startuptype Automatic
```

One potential downside of this approach is that cmdlets that perform an action often don't produce any output indicating that they've done their job. You won't have any visual output from either of the preceding commands, which can be disconcerting. But those cmdlets often have a `-passThru` parameter, which tells them to output whatever objects they accepted as input. You could have Set-Service output the same services it modified, and have Get-Service re-retrieve those services to see if the change took effect.

Here's an example of using `-passThru` with a different cmdlet:

```
Get-Service -name BITS -computer Server1,Server2,Server3 |  
  Start-Service -passthru |  
  Out-File NewServiceStatus.txt
```

This command retrieves the specified service from the three computers listed. The services are then piped to Start-Service, which not only starts them, but also outputs the updated service objects. Those service objects are piped to Out-File, telling it to store the updated service status in a text file.

Once more: this is our recommended way to work in PowerShell. If a cmdlet exists to do whatever you want, you should use it. Ideally, authors write cmdlets to work with batches of objects. That isn't always the case (cmdlet authors are still learning the best ways to write cmdlets for us administrators), but it's the ideal.

16.3 The CIM/WMI way: invoking methods

Unfortunately, we don't always have cmdlets that can take whatever action we need, and that's true when it comes to the items we can manipulate through Windows Management Instrumentation (WMI, which we tackled in chapter 14).

NOTE We'll walk you through a brief storyline meant to help you experience how folks use PowerShell. Some things may seem redundant, but bear with us—the experience itself is valuable.

For example, consider the `Win32_NetworkAdapterConfiguration` class in WMI. This class represents the configuration bound to a network adapter (adapters can have multiple configurations, but for now let's assume they have only one configuration

apiece, which is common on client computers). Let's say that our goal is to enable DHCP on all of our computer's Intel network adapters—we don't want to enable any of the RAS or other virtual adapters.

We might start by trying to query the desired adapter configurations, which would allow us to get something like the following as output:

```
DHCPEnabled      : False
IPAddress       : {192.168.10.10, fe80::ec31:bd61:d42b:66f}
DefaultIPGateway :
DNSDomain       :
ServiceName     : E1G60
Description      : Intel(R) PRO/1000 MT Network Connection
Index           : 7
DHCPEnabled      : True
IPAddress       :
DefaultIPGateway :
DNSDomain       :
ServiceName     : E1G60
Description      : Intel(R) PRO/1000 MT Network Connection
Index           : 12
```

To achieve this output, we'd need to query the appropriate WMI class and filter it to allow only configurations with *Intel* in their descriptions to be included. The following command does that (notice that the % acts as a wildcard within the WMI filter syntax):

```
PS C:\> gwmi win32_networkadapterconfiguration
➥-filter "description like '%intel%'"
```

TRY IT NOW You're welcome to follow along with the commands we're running in this section. You may need to tweak the commands slightly to make them work. For example, if your computer doesn't have any Intel-made network adapters, you need to change the filter criteria appropriately.

Once we have those configuration objects in the pipeline, we want to enable DHCP on them (you can see that one of our adapters doesn't have DHCP enabled). We might start by looking for a cmdlet named something like *Enable-DHCP*. Unfortunately, we won't find it, because there's no such thing. There aren't any cmdlets that are capable of dealing directly with WMI objects in batches.

Our next step is to see whether the object itself has a method that's capable of enabling DHCP. To find out, we pipe those configuration objects to *Get-Member* (or its alias, *Gm*):

```
PS C:\> gwmi win32_networkadapterconfiguration
➥-filter "description like '%intel%' | gm
```

Right near the top of the resulting list, we should see the method we're after, *EnableDHCP()*:

```
TypeName: System.Management.ManagementObject#root\cimv2\Win32_NetworkAd
apterConfiguration
```

Name	MemberType	Definition
-----	-----	-----
DisableIPSec	Method	System.Management.ManagementB...
EnableDHCP	Method	System.Management.ManagementB...
EnableIPSec	Method	System.Management.ManagementB...
EnableStatic	Method	System.Management.ManagementB...

The next step, which a lot of PowerShell newcomers try, is to pipe the configuration objects to the method:

```
PS C:\> gwmi win32_networkadapterconfiguration
➥-filter "description like '%intel%'" | EnableDHCP()
```

Sadly, that won't work. You can't pipe objects to a method; you can pipe only to a cmdlet. `EnableDHCP` isn't a PowerShell cmdlet. Rather, it's an action that's directly attached to the configuration object itself. The old, VBScript-style approach would look a lot like the VBScript example we showed you at the start of this chapter, but with PowerShell you can do something simpler.

Although there's no "batch" cmdlet called `Enable-DHCP`, you can use a generic cmdlet called `Invoke-WmiMethod`. This cmdlet is specially designed to accept a batch of WMI objects, such as our `Win32_NetworkAdapterConfiguration` objects, and to invoke one of the methods attached to those objects. Here's the command we run:

```
PS C:\> gwmi win32_networkadapterconfiguration
➥-filter "description like '%intel%'" |
➥Invoke-WmiMethod -name EnableDHCP
```

You have a few things to keep in mind:

- The method name isn't followed by parentheses.
- The method name isn't case-sensitive.
- `Invoke-WmiMethod` can accept only one kind of WMI object at a time. In this case, we're sending it only `Win32_NetworkAdapterConfiguration` objects, which means it'll work as expected. It's OK to send it more than one object (that's the whole point, in fact), but all of the objects have to be of the same type.
- You can use `-WhatIf` and `-Confirm` with `Invoke-WmiMethod`. But you can't use those when calling a method directly from an object.

The output of `Invoke-WmiMethod` can be a little confusing. WMI always produces a result object, and it has a lot of system properties (whose names start with two underscore characters). In our case, the command produces the following:

```
__GENUS      : 2
__CLASS      : __PARAMETERS
__SUPERCLASS :
__DYNASTY    : __PARAMETERS
__RELPATH    :
__PROPERTY_COUNT : 1
__DERIVATION  : {}
__SERVER     :
__NAMESPACE   :
__PATH       :
```

```
ReturnValue      : 0
__GENUS         : 2
__CLASS          : __PARAMETERS
__SUPERCLASS    :
__DYNASTY        : __PARAMETERS
__RELPATH        :
__PROPERTY_COUNT : 1
__DERIVATION     : { }
__SERVER          :
__NAMESPACE       :
__PATH            :
ReturnValue      : 84
```

The only useful information in the preceding output is the one property that doesn't start with two underscores: `ReturnValue`. That number tells us the result of the operation. A Google search for `Win32_NetworkAdapterConfiguration` turns up the documentation page, and we can then click through to the `EnableDHCP` method to see the possible return values and their meanings. Figure 16.1 shows what we discover.

Return Value	Description
78	File copy failed.
79	Invalid security parameter.
80	Unable to configure TCP/IP service.
81	Unable to configure DHCP service.
82	Unable to renew DHCP lease.
83	Unable to release DHCP lease.
84	IP not enabled on adapter.
85	IDY not enabled on adapter

Figure 16.1 Looking up return values for a WMI method's results

A value of 0 means success, whereas 84 means that the IP isn't enabled on that adapter configuration and DHCP can't be enabled. But which bit of the output goes with which of our two network adapter configurations? It's difficult to tell, because the output doesn't tell you which specific configuration object produces it. That's unfortunate, but it's the way WMI works.

`Invoke-WmiMethod` works for most situations in which you have a WMI object that has a method that you want to execute. It works well when querying WMI objects from remote computers too. Our basic rule is, "If you can get to something by using `Get-WmiObject`, then `Invoke-WmiObject` can execute its methods."

If you recall what you learned in chapter 14, you'll know that `Get-WmiObject` and `Invoke-WmiMethod` are the "legacy" cmdlets for working with WMI; their successors are `Get-CimInstance` and `Invoke-CimMethod`. They work more or less the same way:

```
PS C:\> Get-CimInstance -classname win32_networkadapterconfiguration  
➥-filter "description like '%intel%' " |  
➥Invoke-CimMethod -methodname EnableDHCP
```

In chapter 14, we offered suggestions for when to use WMI or CIM, and those apply here: WMI works with the broadest range of computers (currently), although it requires difficult-to-firewall RPC network traffic; CIM requires the newer and easier WS-MAN traffic, but that isn't installed by default on older versions of Windows.

But wait—there's one more thing. We're discussing WMI in this section, and back in chapter 14 we mentioned that Microsoft had done a lot to inadvertently hide WMI from you, wrapping key WMI functionality (well, technically it's CIM functionality, but close enough) into cmdlets. Try running `help Set-NetIPAddress` in PowerShell. On a newer version of Windows, you'll find a great cmdlet that wraps around much of the underlying WMI/CIM complexity. Instead of all this WMI/CIM fussing, we could have used that cmdlet to change the IP address. That's one of the real lessons here: Even if you've read about something on the internet, don't assume PowerShell v3 or v4 or whatever doesn't offer a better way. Much of what's posted on the internet is based on PowerShell v1 and v2, and the cmdlet coverage in v3 (and later) is at least four or five times better.

16.4 The backup plan: enumerating objects

Unfortunately, we've run across a few situations where `Invoke-WmiMethod` couldn't execute a method—it kept returning weird error messages (`Invoke-CimMethod` is more reliable). We've also run into situations where we have a cmdlet that can produce objects, but we know of no batch cmdlet to which we can pipe those objects to take some kind of action. In either case, you can still perform whatever task you want to perform, but you'll have to fall back on the old VBScript-style approach of instructing the computer to enumerate the objects and perform your task against one object at a time. PowerShell offers two ways to accomplish this: one is using a cmdlet, and the other is using a scripting construct. We focus on the first technique in this chapter, and we save the second for chapter 21, which dives into PowerShell's built-in scripting language.

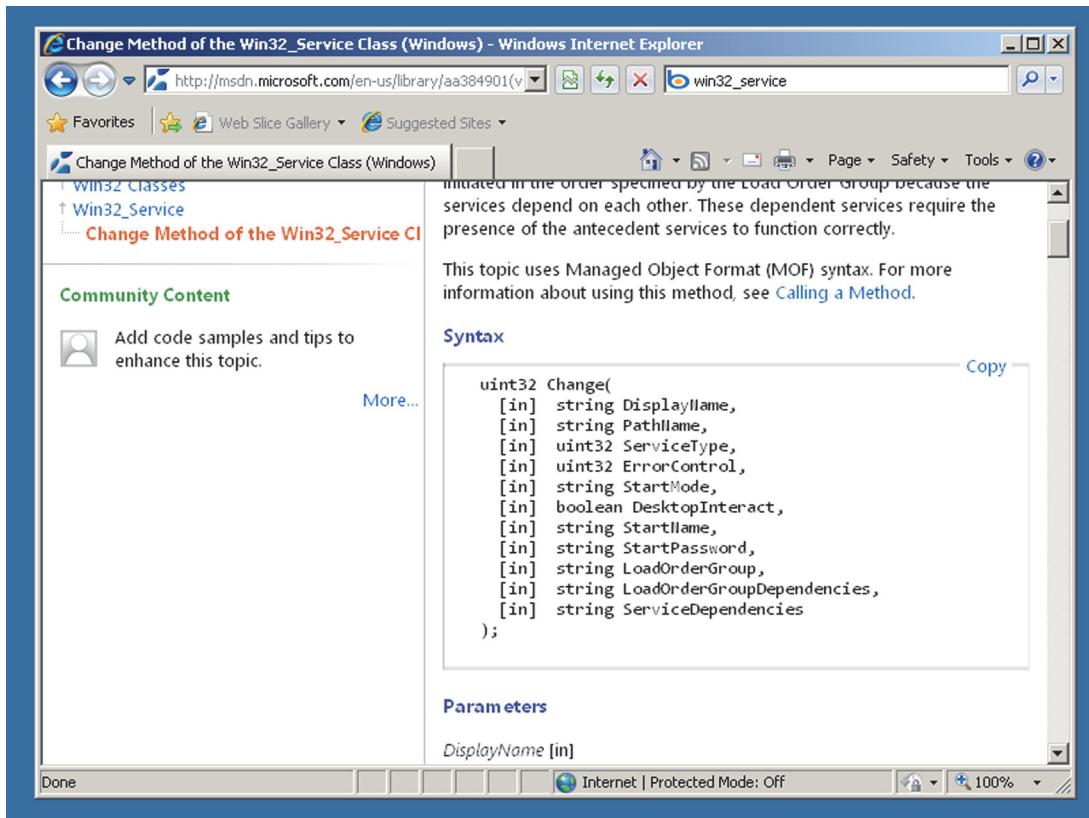

Figure 16.2 Documentation page for the `Change()` method of `Win32_Service`

As an example of how to do this, we'll use the `Win32_Service` WMI class. Specifically, we'll use the `Change()` method. This is a complex method that can change several elements of a service at once. Figure 16.2 shows its online documentation (which we found by searching for `Win32_Service` and then clicking the `Change` method). Reading this page, you'll discover that you don't have to specify every single parameter of the method. You can specify `Null` (which in PowerShell is in the special built-in `$null` variable) for any parameters that you want to omit.

For this example, we want to change the service's startup password, which is the eighth parameter. To do this, we need to specify `$null` for the first seven parameters. That means our method execution might look like the following:

```
Change($null, $null, $null, $null, $null, $null, $null, "P@ssw0rd")
```

By the way, neither `Get-Service` nor `Set-Service` is capable of displaying or setting a service's logon password. But WMI can do it, so we're using WMI.

Because we can't use the Set-Service batch cmdlet, which would normally be our preferred approach, we try our second approach, which is to use Invoke-WmiMethod. The cmdlet has a parameter, -ArgumentList, where we can specify the arguments for the method. The following is an example of our attempt, along with the results we receive:

```
PS C:\> gwmi win32_service -filter "name = 'BITS'" | invoke-wmimethod -name
➥ change -arg $null,$null,$null,$null,$null,$null,"P@ssw0rd"

Invoke-WmiMethod : Input string was not in a correct format.
At line:1 char:62
+ gwmi win32_service -filter "name = 'BITS'" | invoke-wmimethod <<< -nam
e change -arg $null,$null,$null,$null,$null,$null,"P@ssw0rd"
+ CategoryInfo          : NotSpecified: (:) [Invoke-WmiMethod], Forma
tException
+ FullyQualifiedErrorId : System.FormatException,Microsoft.PowerShell
.Commands.InvokeWmiMethod
```

NOTE We're using Get-WmiObject, but Get-CimInstance has virtually the same syntax.

At this point, we have to make a decision. It's possible that we're running the command incorrectly, so we have to decide whether we want to spend a lot of time figuring it out. It's also possible that Invoke-WmiMethod doesn't work well with the Change() method, in which case we could be spending a lot of time trying to fix something over which we have no control.

Our usual choice in these situations is to try a different approach: We're going to ask the computer (well, the shell) to enumerate the service objects, one at a time, and execute the Change() method on each of them, one at a time. To do this, we use the ForEach-Object cmdlet:

```
PS C:\> gwmi win32_service -filter "name = 'BITS'" |
➥ foreach-object {$_.change($null,$null,$null,$null,$null,$null,
➥ $null,"P@ssw0rd") }

__GENUS          : 2
__CLASS         : __PARAMETERS
__SUPERCLASS    :
__DYNASTY       : __PARAMETERS
__RELPATH        :
__PROPERTY_COUNT : 1
__DERIVATION     : {}
__SERVER         :
__NAMESPACE      :
__PATH           :
ReturnValue      : 0
```

In the documentation, we found that a ReturnValue of 0 meant success, which means we've achieved our goal. But let's look at that command in more detail, with some nicer formatting:

```
Get-WmiObject Win32_Service -filter "name = 'BITS'" |
➥ ForEach-Object -process {
➥   $_.change($null,$null,$null,$null,$null,$null,$null,"P@ssw0rd")
➥ }
```

This command has lots going on. The first line should make sense: We're using `Get-WmiObject` to retrieve all instances of `Win32_Service` that match our filter criteria, which is looking for services that have the name `BITS`. (As usual, we're picking on the `BITS` service because it's less essential than some others we could have picked, and breaking it won't crash our computer.) We're piping those `Win32_Service` objects to the `ForEach-Object` cmdlet.

Let's break the previous example into its component elements:

- First, you see the cmdlet name: `ForEach-Object`.
- Next, we use the `-Process` parameter to specify a script block. We didn't originally type the `-Process` parameter name, because it's a positional parameter. But that script block—everything contained within the curly braces—is the value for the `-Process` parameter. We went ahead and included the parameter name when we reformatted the command for easier reading.
- `ForEach-Object` executes its script block once for each object that was piped into `ForEach-Object`. Each time the script block executes, the next piped-in object is placed into the special `$_` placeholder.
- By following `$_` with a period, we're telling the shell we want to access a property or method of the current object.
- In the example, we're accessing the `Change()` method. Note that the method's parameters are passed as a comma-separated list, contained within parentheses. We've used `$null` for the parameters we don't want to change and provided our new password as the eighth parameter. The method accepts more parameters, but because we don't want to change the ninth, tenth, or eleventh ones, we can omit them entirely. (We could also have specified `$null` for the last three parameters.)

We've definitely covered a complicated syntax. Figure 16.3 breaks it down for you.

You can use this exact same pattern for any WMI method. Why would you ever use `Invoke-WmiMethod` instead? Well, it usually does work, and it's a bit easier to type and read. But if you prefer to memorize only one way of doing things, this `ForEach-Object` way works well.

We have to caution you that the examples you see on the internet might be a lot less easy to read. PowerShell gurus often tend to use aliases, positional parameters,

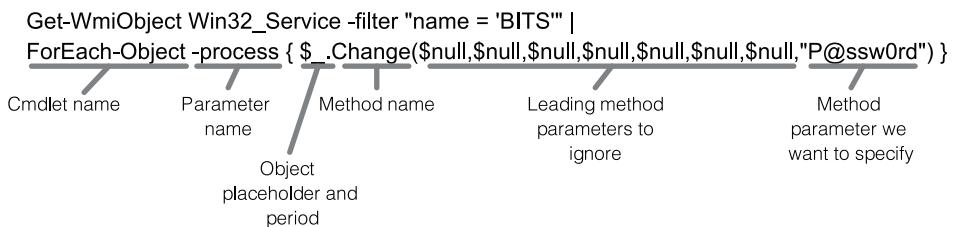

Figure 16.3 Breaking down the `ForEach-Object` cmdlet

and shortened parameter names, which reduces readability (but saves on typing). Here's the same command again, in super-short form:

```
PS C:\> gwmi win32_service -fi "name = 'BITS'" |
  % {$_.Change($null,$null,$null,$null,$null,$null,$null,"P@ssw0rd") }
```

Let's review the changes:

- We use the alias `Gwmi` instead of `Get-WmiObject`.
- We abbreviate `-filter` to `-fi`.
- We use the `%` alias instead of `ForEach-Object`. Yes, the percent sign is an alias to that cmdlet. We find that to be tough to read, but lots of folks use it.
- We remove the `-process` parameter name again, because it's a positional parameter.

We don't like using aliases and abbreviated parameter names when we're sharing scripts, posting them in our blogs, and so forth, because it makes them too difficult for someone else to read. If you're going to save something in a script file, it's worth your time to type everything out (or use Tab completion to let the shell type it out for you).

If you ever want to use this example, there are a few things you might change (as illustrated in figure 16.4):

- Change the WMI class name, and your filter criteria, to retrieve whatever WMI objects you want.
- Modify the method name from `Change` to whatever method you want to execute.
- Modify the method's parameter (also called *argument*) list to whatever your method needs. This is always a comma-separated list contained within parentheses. It's OK for the parentheses to be completely empty for methods that have no parameters, such as the `EnableDHCP()` method we introduced earlier in this chapter.

Was this approach the best way to achieve our goal? Looking at the help for `Set-Service`, we see that it doesn't offer a way to change passwords, which `Get-WmiObject` and `Get-CimInstance` both do. This leads us to conclude that, even in PowerShell v3, WMI is the way to go for this particular task.

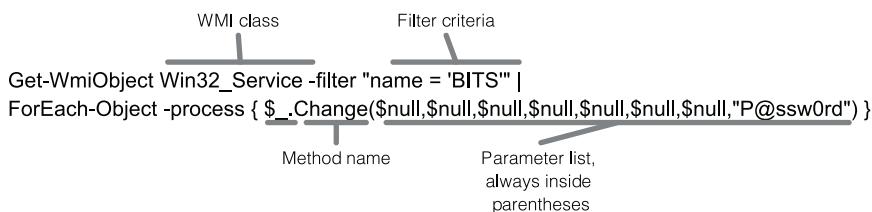

Figure 16.4 The changes you'd make to the previous example to execute a different WMI method

16.5 Common points of confusion

The techniques in this chapter are among the most difficult in PowerShell, and they often cause the most confusion in our classes. Let's look at some of the problems students tend to run into, and provide some alternative explanations that will help you avoid the same issues.

16.5.1 Which way is the right way?

We use the term *batch cmdlet* or *action cmdlet* to refer to any cmdlet that performs an action against a group, or collection, of objects all at once. Rather than having to instruct the computer to "go through this list of things, and perform this one action with each of those things," you can send the whole group to a cmdlet, and the cmdlet handles it.

Microsoft is getting better about providing these kinds of cmdlets with its products, but its coverage isn't 100% yet (and probably won't be for many years, because of the many complex Microsoft products that exist). But when a cmdlet does exist, we prefer to use it. That said, other PowerShell developers prefer alternate ways, depending on what they learned first and what they remember most easily. All of the following are exactly the same:

```
Get-Service -name *B* | Stop-Service          ← ① Batch cmdlet
Get-Service -name *B* | ForEach-Object { $_.Stop() } ← ② ForEach-Object
Get-WmiObject Win32_Service -filter "name LIKE '%B%'" | ← ③ WMI
    ↳ Invoke-WmiMethod -name StopService
Get-WmiObject Win32_Service -filter "name LIKE '%B%'" | ← ④ WMI and
    ↳ ForEach-Object { $_.StopService() }
Stop-Service -name *B*                         ← ⑤ Stop-Service
```

Let's look at how each approach works:

- The first approach is to use a batch cmdlet ①. Here, we're using `Get-Service` to retrieve all services with a *B* in their name, and then stop them.
- The second approach is similar. But rather than using a batch cmdlet, we're piping the services to `ForEach-Object`, and asking it to execute each service's `Stop()` method ②.
- The third technique is to use WMI, rather than the shell's native service management cmdlets ③. We're retrieving the desired services (again, any with *B* in their name), and piping them to `Invoke-WmiMethod`. We're telling it to invoke the `StopService` method, which is the method name that the WMI service objects use.
- The fourth way uses `ForEach-Object` instead of `Invoke-WmiMethod` but accomplishes exactly the same thing ④. This is a combination of ② and ③, not a whole new way of doing things.
- The fifth technique uses `Stop-Service` ⑤ directly, because its `-Name` parameter (in PowerShell v3) accepts wildcards.

Heck, there's even a sixth approach—using PowerShell's scripting language to do the same thing. You'll find lots of ways to accomplish almost anything in PowerShell, and none of them are wrong. Some are easier than others to learn, remember, and repeat, which is why we've focused on the techniques we have, in the order that we did.

Our examples also illustrate important differences between using native cmdlets and WMI:

- Native cmdlets' filtering criteria usually use * as a wildcard character, whereas WMI filtering uses the percent sign (%). Don't confuse that percent sign for the `ForEach-Object` alias. This percent sign is enclosed within the value of `Get-WmiObject`'s `-filter` parameter, and it isn't an alias.
- Native objects often have similar capabilities to WMI ones, but the syntax may differ. In our example, the `ServiceController` objects produced by `Get-Service` have a `Stop()` method; when we access those same services through the WMI `Win32_Service` class, the method name becomes `StopService()`.
- Native filtering often uses native comparison operators, such as `-eq`; WMI uses programming-style operators such as `=` or `LIKE`.

Which should you use? It doesn't matter, because there's no right way. You may even end up using a mix of these, depending on the circumstances and the capabilities that the shell is able to offer you for the task at hand.

16.5.2 WMI methods vs. cmdlets

When should you use a WMI method or a cmdlet to accomplish a task? It's a simple choice:

- If you retrieve something by using `Get-WmiObject`, take action on that something by using a WMI method. You can execute the method by using `Invoke-WmiMethod` or the `ForEach-Object` approach.
- If you retrieve something by using an approach other than `Get-WmiObject`, use a native cmdlet to take action against that something. Or, if whatever you retrieve has a method but no supporting cmdlet, you might use the `ForEach-Object` approach to execute that method.

Notice that the lowest common denominator here is `ForEach-Object`: Its syntax is perhaps the most difficult, but you can always use it to accomplish whatever task you need to do.

You can never pipe anything to a method. You can pipe only from one cmdlet to another. If a cmdlet doesn't exist to do what you need, but a method does, then you pipe to `ForEach-Object` and have it execute the method.

For example, suppose you retrieve something by using a `Get-Something` cmdlet. You want to delete that something, but there's no `Delete-Something` or `Remove-Something` cmdlet. But the `Something` objects do have a `Delete` method. You can do this:

```
Get-Something | ForEach-Object { $_.Delete() }
```

16.5.3 Method documentation

Always remember that piping objects to `Get-Member` reveals methods. Again, let's use the fictional `Get-Something` cmdlet as an example:

```
Get-Something | Get-Member
```

PowerShell's built-in help system doesn't document WMI methods; you need to use a search engine (usually searching on the WMI class name) to locate WMI method instructions and examples. You also won't find methods of non-WMI objects documented in PowerShell's built-in help system. For example, if you get a member list for a service object, you can see that methods named `Stop` and `Start` exist:

TypeName: System.ServiceProcess.ServiceController			
Name	MemberType	Definition	
-----	-----	-----	-----
Name	AliasProperty	Name = ServiceName	
RequiredServices	AliasProperty	RequiredServices = ServicesDepe...	
Disposed	Event	System.EventHandler Disposed(Sy...	
Close	Method	System.Void Close()	
Continue	Method	System.Void Continue()	
CreateObjRef	Method	System.Runtime.Remoting.ObjRef ...	
Dispose	Method	System.Void Dispose()	
Equals	Method	bool Equals(System.Object obj)	
ExecuteCommand	Method	System.Void ExecuteCommand(int ...	
GetHashCode	Method	int GetHashCode()	
GetLifetimeService	Method	System.Object GetLifetimeService()	
GetType	Method	type GetType()	
InitializeLifetimeService	Method	System.Object InitializeLifetim...	
Pause	Method	System.Void Pause()	
Refresh	Method	System.Void Refresh()	
Start	Method	System.Void Start(), System.Voi...	
Stop	Method	System.Void Stop()	
ToString	Method	string ToString()	
WaitForStatus	Method	System.Void WaitForStatus(Syste...	

To find the documentation for these, focus on the `TypeName`, which in this case is `-System.ServiceProcess.ServiceController`. Search for that complete type name in a search engine, and you'll usually come across the official developer documentation for that type, which will lead to the documentation for the specific method you're after.

16.5.4 ForEach-Object confusion

The `ForEach-Object` cmdlet has a punctuation-heavy syntax, and adding in a method's own syntax can create an ugly command line. We've compiled some tips for breaking any mental logjams:

- Try to use the full cmdlet name instead of its % or `ForEach` alias. The full name can be easier to read. If you're using someone else's example, replace aliases with the full cmdlet names.

- The script block enclosed in curly braces executes once for each object that's piped into the cmdlet.
- Within the script block, the `$_` represents one of the piped-in objects.
- Use `$_` by itself to work with the entire object you piped in; follow `$_` with a period to work with individual methods or properties.
- Method names are always followed by parentheses, even if the method doesn't require any parameters. When parameters are required, they're delimited by commas and included within the parentheses.

16.6 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

Try to answer the following questions and complete the specified tasks. This is an important lab, because it draws on skills you've learned in many previous chapters, and you should be continuing to use and reinforce these skills as you progress through the remainder of this book.

- 1 What method of a `ServiceController` object (produced by `Get-Service`) will pause the service without stopping it completely?
- 2 What method of a `Process` object (produced by `Get-Process`) would terminate a given process?
- 3 What method of a WMI `Win32_Process` object would terminate a given process?
- 4 Write four commands that could be used to terminate all processes named Notepad, assuming that multiple processes might be running under that same name.
- 5 Assume you have a text list of computer names but want to display them in all uppercase. What PowerShell expression could you use?

16.7 Lab answers

- 1 Find the methods like this: `get-service | Get-Member -MemberType Method` and you should see a `Pause()` method.
- 2 Find the methods like this: `get-process | Get-Member -MemberType Method` and you should see a `Kill()` method. You could verify by checking the MSDN documentation for this process object type. Of course you shouldn't need to invoke the method because there is a cmdlet, `Stop-Process`, that will do the work for you.
- 3 You could search the MSDN documentation for the `Win32_Process` class. Or you might use the CIM cmdlets because they also work with WMI to list all possible methods.
`Get-CimClass win32_process | select -ExpandProperty methods`
In either event, you should see the `Terminate()` method.

```
4 get-process Notepad | stop-process  
stop-process -name Notepad  
get-process notepad | foreach {$_.Kill()}  
Get-WmiObject win32_process -filter {name='notepad.exe'} |  
Invoke-WmiMethod -Name Terminate  
5 Get-content computers.txt | foreach {$_.ToUpper()}
```

17

Security alert!

By now, you’re probably starting to get a feel for how powerful PowerShell can be—and you’re wondering whether all that power might be a security problem. It *might* be. Our goal in this chapter is to help you understand exactly how PowerShell can impact security in your environment, and how to configure PowerShell to provide exactly the balance of security and power you require. Also, pretty much everything in this chapter is specific to the Windows editions of PowerShell; macOS and Linux don’t include most of these features, as they’re not in keeping with the traditional shell experience on those platforms.

17.1 **Keeping the shell secure**

When PowerShell was introduced in late 2006, Microsoft didn’t exactly have a spotless record on security and scripting. After all, VBScript and Windows Script Host (WSH) were probably two of the most popular virus and malware vectors of the time, serving as entry points for such infamous viruses as I Love You, Melissa, and many others. When the PowerShell team announced that they were creating a new command-line shell that would offer unprecedented power and functionality, as well as scripting capabilities, we’re sure alarms went off, people were evacuated from buildings, and everyone gnashed their teeth in dismay.

But it’s OK. PowerShell was created after the famous Trustworthy Computing Initiative that Bill Gates started within Microsoft. That initiative had a real effect within the company: Each product team is required to have a skilled software security expert sit in on their design meetings, code reviews, and so forth. That expert is referred to as—and we’re not making this up—the product’s *Security Buddy*.

PowerShell's Security Buddy was one of the authors of *Writing Secure Code*, Microsoft's own bible for writing software that's less easily exploited by attackers. You can be assured that PowerShell is as secure as any such product can possibly be—at least, it's that secure by default. Obviously, you can change the defaults, but when you do that, you should consider the security ramifications, and not only the functional ones. That's what this chapter will help you accomplish.

17.2 Windows PowerShell security goals

We need to be clear about what PowerShell does and doesn't do when it comes to security, and the best way to do that is to outline some of PowerShell's security goals.

First and foremost, PowerShell doesn't apply any additional layers of permissions on anything it touches. PowerShell enables you to do only what you already have permission to do. If you can't create new users in Active Directory by using the graphical console, you won't be able to do so in PowerShell either. PowerShell is another means of exercising whatever permissions you already have.

PowerShell is also not a way to bypass any existing permissions. Let's say you want to deploy a script to your users, and you want that script to do something that your users don't normally have permission to do. That script isn't going to work for them. If you want your users to do something, you need to give them permission to do it; PowerShell can accomplish only those things that the person running a command or script already has permission to do.

PowerShell's security system isn't designed to prevent anyone from typing in, and running, whatever commands they have permission to execute. The idea is that it's somewhat difficult to trick a user into typing a long, complicated command, so PowerShell doesn't apply any security beyond the user's existing permissions. But we know from past experience that it's easy to trick users into running a script, which might well contain malicious commands. This is why most of PowerShell's security is designed with the goal of preventing users from unintentionally running scripts. The *unintentionally* part is important: Nothing in PowerShell's security is intended to prevent a determined user from running a script. The idea is to prevent users only from being *tricked* into running scripts from untrusted sources.

Above and beyond

It's beyond the scope of this book, but we do want you to be aware of other ways to let your users execute a script that runs under credentials other than their own. You can typically accomplish this through a technique called *script packaging*, a feature of some commercial script development environments such as SAPIEN PowerShell Studio (www.sapien.com).

After creating a script, you use the packager to bundle the script into an executable (.EXE) file. This isn't compilation in the programming sense of the term: The executable isn't standalone, and it requires that PowerShell be installed in order to run. You can configure the packager to encrypt alternative credentials into the executable.

(continued)

That way, when someone runs the executable, it launches the packaged script under whatever credentials you specify, rather than under the user's own credentials.

The packaged credentials aren't 100% safe. The package does include the username and password, although most packagers adequately encrypt them. It's safe to say that most users won't be able to discover the username and password, but it's completely possible for a skilled encryption expert to decrypt the username and password.

PowerShell's security is also not a defense against malware. Once you have malware on your system, that malware can do anything you have permission to do. It might use PowerShell to execute malicious commands, but it might as easily use any of a dozen other techniques to damage your computer. Once you have malware on your system, you're "owned," and PowerShell isn't a second line of defense. You'll continue to need antimalware software to prevent malware from getting onto your system in the first place. This is a hugely important concept that a lot of people miss: Even though a piece of malware might use PowerShell to do harm, that doesn't make that malware PowerShell's problem. Your antimalware software must stop the malware. Nothing in PowerShell is designed or intended to protect an already compromised system.

17.3 Execution policy and code signing

The first security measure PowerShell includes is an *execution policy*. This machine-wide setting governs the scripts that PowerShell will execute. As we stated earlier in this chapter, the intent of this setting is to help prevent users from being tricked into running a script.

17.3.1 Execution policy settings

The default setting is `Restricted`, which prevents scripts from being executed at all. That's right: By default, you can use PowerShell to interactively run commands, but you can't use it to run scripts. If you try, you'll get the following error message:

```
File C:\test.ps1 cannot be loaded because the execution of scripts is disabled on this system. Please see "get-help about_signing" for more details.  
At line:1 char:7  
+ ./test <<<  
+ CategoryInfo          : NotSpecified: (:) [], PSSecurityException  
+ FullyQualifiedErrorId : RuntimeException
```

You can view the current execution policy by running `Get-ExecutionPolicy`. You can change the execution policy in one of three ways:

- *By running the `Set-ExecutionPolicy` command.* This changes the setting in the `HKEY_LOCAL_MACHINE` portion of the Windows Registry and usually must be run

by an administrator, because regular users don't have permission to write to that portion of the Registry.

- By using a *Group Policy object (GPO)*. Starting with Windows Server 2008 R2, support for Windows PowerShell-related settings is included. If for some reason you are stuck with an older domain (our condolences), you can try searching for the PowerShell ADM template at download.microsoft.com.

As shown in figure 17.1, the PowerShell settings are located under Computer Configuration > Policies > Administrative Templates > Windows Components > Windows PowerShell. Figure 17.2 displays the policy setting as enabled. When configured via a Group Policy object, the setting in the Group Policy overrides any local setting. In fact, if you try to run `Set-ExecutionPolicy`, it'll work, but a warning message will tell you that your new setting had no effect because of a Group Policy override.

- By manually running `PowerShell.exe` and using its `-ExecutionPolicy` command-line switch. When you run it in this fashion, the specified execution policy overrides any local setting as well as any Group Policy-defined setting.

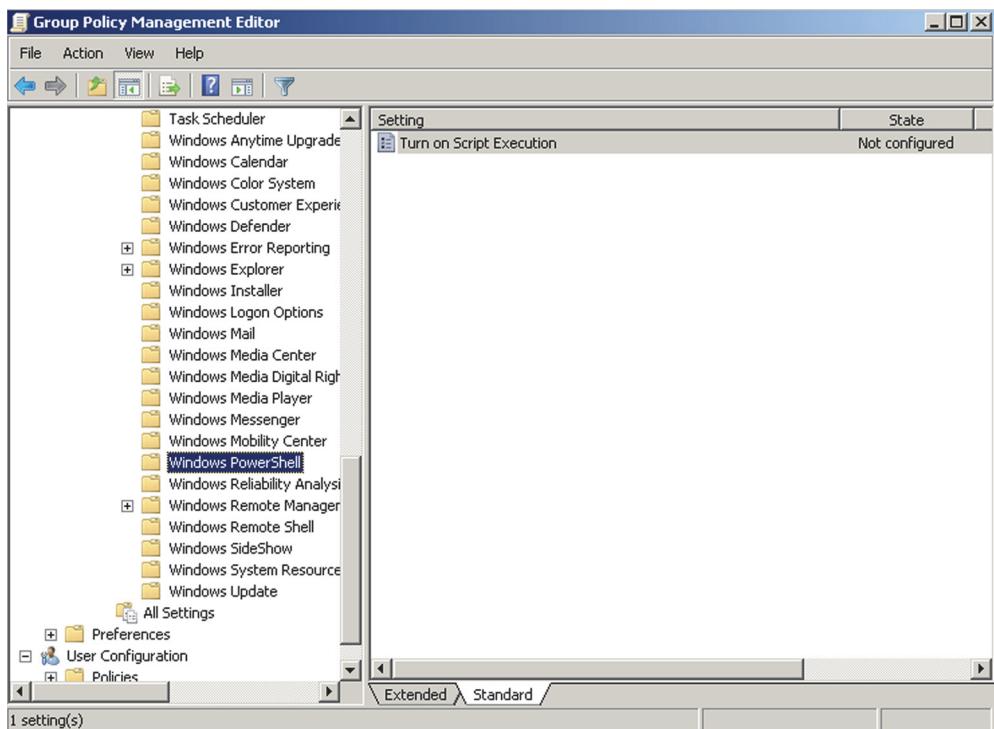

Figure 17.1 Finding the Windows PowerShell settings in a Group Policy object

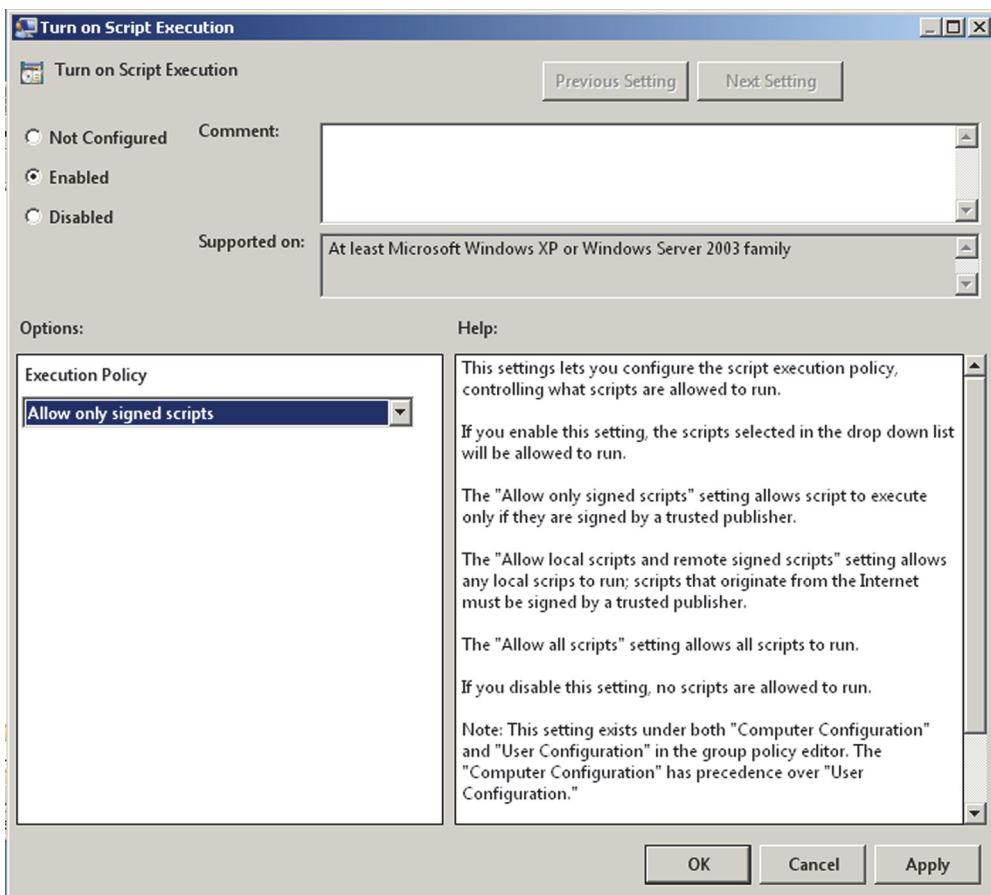

Figure 17.2 Changing the Windows PowerShell execution policy in a Group Policy object

You can set the execution policy to one of five settings (note that the Group Policy object provides access to only the middle three of the following list):

- **Restricted**—This is the default, and scripts aren't executed. The only exceptions are a few Microsoft-supplied scripts that set up PowerShell's default configuration settings. Those scripts carry a Microsoft digital signature and won't execute if modified.
- **AllSigned**—PowerShell will execute any script that has been digitally signed by using a code-signing certificate issued by a trusted certification authority (CA).
- **RemoteSigned**—PowerShell will execute any local script, and will execute remote scripts if they've been digitally signed by using a code-signing certificate issued by a trusted CA. *Remote scripts* are those that exist on a remote computer, usually accessed by a Universal Naming Convention (UNC) path. Scripts marked as having come from the internet are also considered remote; Internet

Explorer, Firefox, and Outlook all mark downloads as having come from the internet. Some versions of Windows can distinguish between internet paths and UNC paths; in those cases, UNC paths on the local network aren't considered remote.

- Unrestricted—All scripts will run.
- Bypass—This special setting is intended for use by application developers who are embedding PowerShell within their application. This setting bypasses the configured execution policy and should be used only when the hosting application is providing its own layer of script security. You're essentially telling PowerShell, "Don't worry. I have security covered."

Wait, what?

Did you notice that you could set the execution policy in a Group Policy object, but also override it by using a parameter of `PowerShell.exe`? What good is a GPO-controlled setting that people can easily override? This emphasizes that the execution policy is intended to protect only *uninformed* users from *unintentionally* running *anonymous* scripts.

The execution policy isn't intended to stop an informed user from doing anything intentional. It's not that kind of security setting.

In fact, a smart malware coder could as easily access the .NET Framework functionality directly, without going to the trouble of using PowerShell as a middleman. Or to put it another way, if an unauthorized user has admin rights to your computer and can run arbitrary code, you're already in trouble.

Microsoft recommends that you use `RemoteSigned` when you want to run scripts, and that you use it only on computers where scripts must be executed. According to Microsoft, all other computers should be left at `Restricted`. The company says that `RemoteSigned` provides a good balance between security and convenience; `AllSigned` is stricter but requires all of your scripts to be digitally signed. The PowerShell community as a whole is more divided, with a range of opinions on what a good execution policy is. For now, we'll go with Microsoft's recommendation and let you explore the topic more on your own, if you wish.

This is a good time for us to discuss digital signing in depth.

NOTE Plenty of experts, including Microsoft's own "Scripting Guy," suggest using the `Unrestricted` setting for `ExecutionPolicy`. Their feeling is that the feature doesn't provide a layer of security, and you shouldn't give yourself false confidence that it's protecting you from anything.

17.3.2 Digital code signing

Digital code signing, or *code signing* for short, is the process of applying a cryptographic signature to a text file. Signatures appear at the end of the file and look like the following:

```
<!-- SIG # Begin signature block -->
<!-- MIIXXAYJKoZIhvcNAQcCoIIXTCCF0kCAQEExCzAJBgUrDgMCGgUAMGkGCisGAQQB -->
<!-- gjcCAQSgWzBZMDQGCisGAQQBgjcCAR4wJgIDAQABBAfzDtqWUsITrck0sYpfvNR -->
<!-- AgEAAgEEAgEAAgEAMCEwCQYFKw4DAh0FAAUUJ7qroHx47PI1dIt4lBg6Y5Jo -->
<!-- UVigghIxMIEYDCCA0ygAwIBAgIKLqsR3FD/XJ3LwDAJBgUrDgMCHQUAMHAxKzAp -->
<!-- YjccN4FqI4n2XG0PsFq70ddgjFWEGjP105iggyiX4uzLLehpcur2iC2vzAZhSAU -->
<!-- DSq8UvRB4F4w45IoaYFBcOLzp6v0gEJydg4wggR6MIIDYqADAgECAgphBieBAAA -->
<!-- ZngnZui2t++Fuc3uqv0SpAtZIikvz0DZVgQbdrtZG1KVnv8d6/n4PHgN9/TAI3 -->
<!-- an/xvmG4PNGSdjy8Dcb5otiSjgByprAttPPf2EKUQrFPzREgZabAatwMKJbeRS4 -->
<!-- kd6Qy+RwkCn1UW1eaChbs0LJhix0jm38/pLCCOo1nL79E1sxJumCe6GtqjdWOIBn -->
<!-- KKe66D/GX7eGrfCVg2Vzgp4gG7fHADFEh3OcIvoILWc= -->
<!-- SIG # End signature block -->
```

The signature contains two important pieces of information: First, it lists the identity of the company or organization that signed the script. Second, it includes an encrypted copy of the script, which PowerShell can decrypt. Understanding how this works requires a bit of background information, which will also help you make some important decisions about security in your environment.

To create a digital signature, you need to have a code-signing certificate. Also referred to as *Class 3 certificates*, these are available from commercial CAs such as DigiCert, GoDaddy, Thawte, Verisign, and others. You might also obtain one from your company's internal public-key infrastructure (PKI), if you have one. Class 3 certificates are normally issued only to organizations and companies, not to individuals, although your company may issue them internally to specific users. Before issuing a certificate, the CA is responsible for verifying the identity of the recipient—the certificate is a kind of digital identification card, listing the holder's name and other details. Before issuing a certificate to XYZ Corporation, for example, a CA needs to verify that an authorized representative of XYZ Corporation is making the request. This verification process is the single most important step in the entire security framework, and you should trust a CA only if you know it does a good job of verifying the identities of the companies to which it issues certificates. If you're not familiar with a CA's verification procedures, you *should not trust* that CA.

Trust is configured in the Windows Internet Properties control panel (and can also be configured by Group Policy). In that control panel, select the Content tab, and then click Publishers. In the resulting dialog box, select the Trusted Root Certification Authorities tab. As shown in figure 17.3, you'll see a list of the CAs that your computer trusts.

When you trust a CA, you also trust all certificates issued by it. If someone uses a certificate to sign a malicious script, you can use the signature itself to track down the author—that's why signed scripts are considered more “trusted” than unsigned scripts. But if you place your trust in a CA that does a bad job of verifying identities, a

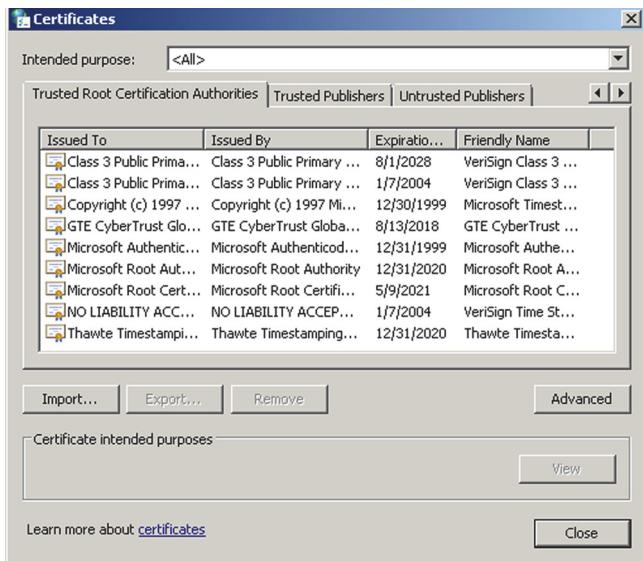

Figure 17.3 Configuring your computer's Trusted Root Certification Authorities

malicious script author might be able to obtain a fraudulent certificate, and you wouldn't be able to use their signature to track them down. That's why choosing which CAs to trust is such a big responsibility.

Once you've obtained a Class 3 certificate (specifically, you need one packaged as an Authenticode certificate—CAs usually offer different varieties for different operating systems and programming languages), you install it on your computer. Once installed, you can then use PowerShell's `Set-AuthenticodeSignature` cmdlet to apply a digital signature to a script. Run `help about_signing` in the shell to learn more. Many commercial script development environments (PowerShell Studio, PowerShell Plus, PowerGUI, and others) can also apply signatures, and can even do that automatically when you save a script, making the signing process more transparent for you.

Signatures not only provide information about the script author's identity, but also ensure that the script hasn't been modified since the author signed it. This works as follows:

- 1 The script author holds a digital certificate, which consists of two cryptographic keys: a public key and a private key.
- 2 When signing a script, the signature is encrypted using the private key. Only the script author has access to that key, and only the public key can decrypt the signature. The signature contains a copy of the script.
- 3 When PowerShell runs the script, it uses the author's public key (which is included along with the signature) to decrypt the signature. If the decryption fails, the signature was tampered with, and the script won't run. If the copy of the script within the signature doesn't match the clear-text copy, the signature is considered broken, and the script won't run.

Figure 17.4 illustrates the entire process that PowerShell goes through when trying to run a script. You can see how the AllSigned execution policy is somewhat more secure: Under that setting, only scripts containing a signature execute, meaning that you can always identify a script's author. You also have to sign every script you want to run, and re-sign them any time you change them, which can be inconvenient.

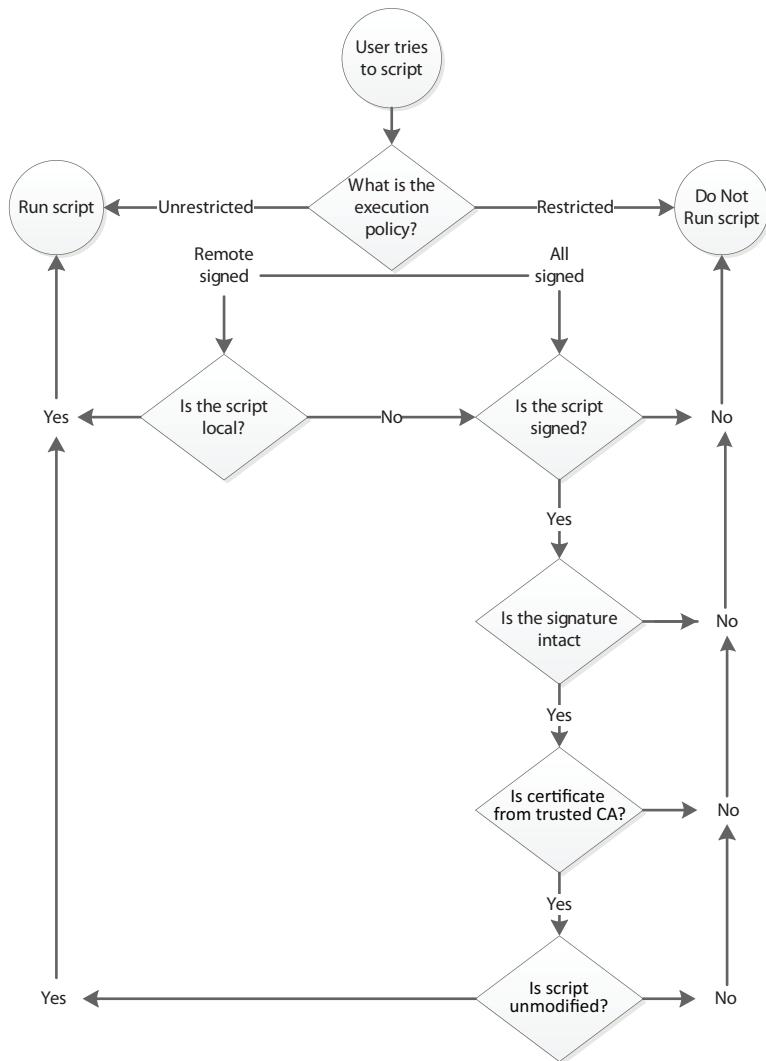

Figure 17.4 The process PowerShell follows when attempting to execute a script

17.4 Other security measures

PowerShell has two other key security measures that are in effect at all times, and they shouldn't be modified.

First, Windows doesn't consider the .PS1 filename extension (which is what the shell uses to identify PowerShell scripts) an executable file type. Double-clicking a .PS1 file normally opens it in Notepad for editing, rather than executing it. This configuration is intended to help prevent users from unknowingly executing a script, even if the execution policy would allow it.

Second, you can't run a script within the shell by typing its name. The shell never searches the current directory for scripts, which means if you have a script named test.ps1, changing to its folder and typing test or test.ps1 won't run the script.

Here's an example:

```
PS C:\> test

The term 'test' is not recognized as the name of a cmdlet, function, script
file, or operable program. Check the spelling of the name, or if a path
was included, verify that the path is correct and try again.
At line:1 char:5
+ test <<<
    + CategoryInfo          : ObjectNotFound: (test:String) [], CommandNo
tFoundException
    + FullyQualifiedErrorId : CommandNotFoundException
Suggestion [3,General]: The command test was not found, but does exist in t
he current location. Windows PowerShell doesn't load commands from the curr
ent location by default. If you trust this command, instead type ".\test".
See "get-help about_Command_Precedence" for more details.
PS C:\>
```

As you can see, PowerShell does detect the script but warns that you have to type either an absolute or relative path in order to run the script. Because the script is located in C:, you could run either C:\test, which is an absolute path, or .\test, which is a relative path that points to the current folder.

The purpose of this security feature is to guard against a type of attack called *command hijacking*. The attack involves putting a script into a folder and giving it the same name as a built-in command, such as Dir. With PowerShell, you never put a path in front of a command name—if you run Dir, you know you're running the command; if you run .\Dir, you know you're running a script named Dir.ps1.

17.5 Other security holes?

As we discussed earlier in this chapter, PowerShell's security focuses primarily on preventing users from unknowingly running untrusted scripts. No security measures can stop a user from manually typing commands into the shell, or from copying the entire contents of a script and pasting them into the shell (although the commands might not have the same effect when run in that fashion). It's a little more difficult to convince a user to do that, and to explain to them how to do it, which is why Microsoft didn't focus on that scenario as a potential attack vector. But remember, PowerShell

doesn't grant your users any additional permissions—they'll be able to do only those things that you've permitted them to do.

Someone could call a user on the phone, or send an email, and walk them through the process of opening PowerShell, typing a few commands, and damaging their computer. But that same someone could also talk a user through an attack using something other than PowerShell. It'd be as easy (or difficult, depending on your viewpoint) to convince a user to open Explorer, select the Program Files folder, and hit Delete on the keyboard. In some ways, that would be easier than walking a user through the equivalent PowerShell command.

We point this out only because people tend to get nervous about the command line and its seemingly infinite reach and power, but the fact is that you and your users can't do anything with the shell that you couldn't do in a half-dozen other ways.

17.6 Security recommendations

As we mentioned earlier, Microsoft recommends the use of the RemoteSigned execution policy for computers where you need to run scripts. You can also consider using AllSigned or even Unrestricted.

AllSigned is a bit less convenient, but you can make it more convenient by following these two recommendations:

- Commercial CAs charge up to \$900 per year for a code-signing certificate. If you don't have an internal PKI that can provide a free one, you can make your own. Run `help about_signing` for information on obtaining and using `Makecert.exe`, a tool that can make a certificate that will be trusted only by your local computer. If that's the only place where you need to run scripts, it's a quick and free way to obtain a certificate. Depending on your version of PowerShell, you might also have a cmdlet called `New-SelfSignedCertificate`, which does the same thing.
- Edit scripts in one of the editors we mentioned, each of which can sign the script for you each time you save the file. That makes the signing process transparent and automatic, making it more convenient.

As we've already stated, we don't think you should change the .PS1 filename association. We've seen some folks modify Windows to recognize .PS1 as an executable, meaning that you can double-click a script to run it. That takes us right back to the bad old days of VBScript, and you probably want to avoid that.

We want to point out that none of the scripts we supply as part of this book are digitally signed. It's possible for these to be modified without our (or your) knowledge. Before you run any of these scripts, you should take the time to review them, understand what they're supposed to do, and make sure they match what's in this book (if appropriate). We didn't sign the scripts specifically because we *want you to take that time*: You should be in the habit of carefully reviewing anything you download from the internet, no matter how "trusted" the author may seem.

17.7 Lab

NOTE For this lab, you need any Windows computer running PowerShell v3 or later.

Your task in this lab is simple—so simple, in fact, that we don’t even provide a sample solution. We want you to configure your shell to allow script execution. Use the `Set-ExecutionPolicy` cmdlet, and we suggest using the `RemoteSigned` policy setting. You’re welcome to use `AllSigned`, but it’ll be impractical for the purposes of this book’s remaining labs. You could also choose `-Unrestricted`.

That said, if you’re using PowerShell in a production environment, please make sure that the execution policy setting you choose is compatible with your organization’s security rules and procedures. We don’t want you getting in trouble for the sake of this book and its labs.

18

Variables: a place to store your stuff

We've already mentioned that PowerShell contains a scripting language, and in a few more chapters we'll start to play with it. But once you start scripting, you tend to need *variables*, so we'll get those out of the way in this chapter. You can use variables in a lot of places other than long, complex scripts, so we'll also use this chapter to show you some practical ways to use them.

18.1 **Introduction to variables**

A simple way to think of a *variable* is as a box in the computer's memory that has a name. You can put whatever you want into the box: a single computer name, a collection of services, an XML document, and so on. You access the box by using its name, and when accessing it, you can put things in it, add things to it, or retrieve things from it. Those things stay in the box, allowing you to retrieve them over and over.

PowerShell doesn't place a lot of formality around variables. For example, you don't have to explicitly announce or declare your intention to use a variable before you do so. You can also change the types of the contents of a variable: One moment you might have a single process in it, and the next moment you can store a bunch of computer names in it. A variable can even contain multiple different things, such as a collection of services *and* a collection of processes (although we admit that, in those cases, using the variable's contents can be tricky).

18.2 Storing values in variables

Everything in PowerShell—and we do mean *everything*—is treated as an object. Even a simple string of characters, such as a computer name, is considered an object. For example, piping a string to `Get-Member` (or its alias, `gm`) reveals that the object is of the type `System.String` and that it has a great many methods you can work with (we’re truncating the following list to save space):

```
PS C:\> "SERVER-R2" | gm

TypeName: System.String
Name          MemberType
----          -----
Clone         Method
CompareTo    Method
Contains      Method
CopyTo        Method
EndsWith     Method
Equals        Method
GetEnumerator Method
GetHashCode   Method
GetType       Method
GetTypeCode   Method
IndexOf       Method
IndexOfAny   Method

Name          MemberType
----          -----
System.Object Clone()
int CompareTo(System.Object valu...
bool Contains(string value)
System.Void CopyTo(int sourceInd...
bool EndsWith(string value), boo...
bool Equals(System.Object obj), ...
System.CharEnumerator GetEnumerator()
int GetHashCode()
type GetType()
System.TypeCode GetTypeCode()
int IndexOf(char value), int Ind...
int IndexOfAny(char[] anyOf), in...
```

TRY IT NOW Run this same command in PowerShell to see if you get the complete list of methods—and even a property—that comes with a `System.String` object.

Although that string is technically an object, like everything else in the shell, you’ll find that folks tend to refer to it as a simple *value*. That’s because, in most cases, what you’re concerned about is the string itself—"SERVER-R2" in the previous example—and you’re less concerned about retrieving information from properties. That’s different from, say, a process, where the entire process object is a big, abstract data construct, and you’re usually dealing with individual properties such as VM, PM, Name, CPU, ID, and so forth. A String is an object, but it’s a much less complicated object than something like a Process.

PowerShell allows you to store these simple values in a variable. To do this, specify the variable, and use the equals sign operator—the *assignment operator*—followed by whatever you want to put within the variable. Here’s an example:

```
PS C:\> $var = "SERVER-R2"
```

TRY IT NOW Follow along with these examples, because then you’ll be able to replicate the results we demonstrate. You should use your test server’s name rather than SERVER-R2.

It’s important to note that the dollar sign (\$) isn’t part of the variable’s name. In our example, the variable name is `var`. The dollar sign is a cue to the shell that what follows

is going to be a variable name, and that we want to access the contents of that variable. In this case, we're setting the contents of the variable.

Let's look at some key points to keep in mind about variables and their names:

- Variable names usually contain letters, numbers, and underscores, and it's most common for them to begin with a letter or an underscore.
- Variable names can contain spaces, but the name must be enclosed in curly braces. For example, \${My Variable} represents a variable named My Variable. Personally, we dislike variable names that contain spaces because they require more typing and they're harder to read.
- Variables don't persist between shell sessions. When you close the shell, any variables you created go away.
- Variable names can be quite long—long enough that you don't need to worry about how long. Try to make variable names sensible. For example, if you'll be putting a computer name into a variable, use computername as the variable name. If a variable will contain a bunch of processes, then processes is a good variable name.
- Except for folks who have a VBScript background, PowerShell users don't typically use variable name prefixes to indicate what's stored in the variable. For example, in VBScript, strComputerName was a common type of variable name, indicating that the variable stored a string (the str part). PowerShell doesn't care whether you do that, but it's no longer considered a desirable practice by the community at large.

To retrieve the contents of a variable, use the dollar sign followed by the variable name, as shown in the following example. Again, the dollar sign tells the shell that you want to access the *contents* of a variable; following it with the variable name tells the shell which variable you're accessing.

```
PS C:\> $var  
SERVER-R2
```

You can use a variable in place of a value in almost any situation. For example, when using WMI, you have the option to specify a computer name. The command might normally look like this:

```
PS C:\> get-wmiobject win32_computersystem -comp SERVER-R2  
Domain : company.pri  
Manufacturer : VMware, Inc.  
Model : VMware Virtual Platform  
Name : SERVER-R2  
PrimaryOwnerName : Windows User  
TotalPhysicalMemory : 3220758528
```

You can substitute a variable for any of the values:

```
PS C:\> get-wmiobject win32_computersystem -comp $var
```

```

Domain           : company.pri
Manufacturer    : VMware, Inc.
Model           : VMware Virtual Platform
Name            : SERVER-R2
PrimaryOwnerName : Windows User
TotalPhysicalMemory : 3220758528

```

By the way, we realize that var is a pretty generic variable name. We'd normally use computername, but in this specific instance we plan to reuse \$var in several situations, so we decided to keep it generic. Don't let this example stop you from using more sensible variable names in real life.

We may have put a string into \$var to begin with, but we can change that anytime we want:

```

PS C:\> $var = 5
PS C:\> $var | gm

TypeName: System.Int32
Name      MemberType Definition
-----
CompareTo Method     int CompareTo(System.Object value), int CompareT...
Equals    Method     bool Equals(System.Object obj), bool Equals(int ...
GetHashCode Method    int GetHashCode()
GetType   Method     type GetType()
GetTypeCode Method   System.TypeCode GetTypeCode()
ToString  Method    string ToString(), string ToString(string format...)

```

In the preceding example, we placed an integer into \$var, and then we piped \$var to `gm`. You can see that the shell recognizes the contents of \$var as a `System.Int32`, or a 32-bit integer.

18.3 Using variables: fun tricks with quotes

Because we're talking about variables, this is a good time to cover a neat PowerShell feature. To this point in the book, we've advised you to generally enclose strings within single quotation marks. The reason for that is PowerShell treats everything enclosed in single quotation marks as a literal string.

Consider the following example:

```

PS C:\> $var = 'What does $var contain?'
PS C:\> $var
What does $var contain?

```

Here you can see that the \$var within single quotes is treated as a literal.

But in double quotation marks that's not the case. Check out the following trick:

```

PS C:\> $computername = 'SERVER-R2'
PS C:\> $phrase = "The computer name is $computername"
PS C:\> $phrase
The computer name is SERVER-R2

```

We start our example by storing SERVER-R2 in the variable \$computername. Next we store "The computer name is \$computername" in the variable \$phrase. When we do

this, we use double quotes. PowerShell automatically seeks out dollar signs within double quotes, and replaces any variables it finds *with their contents*. Because we display the contents of \$phrase, \$computername is replaced with SERVER-R2, the contents of the variable.

This replacement action happens only when the shell initially parses the string. At this point, \$phrase contains "The computer name is SERVER-R2"—it doesn't contain the "\$computername" string. We can test that by trying to change the contents of \$computername to see whether \$phrase updates itself:

```
PS C:\> $computername = 'SERVER1'  
PS C:\> $phrase  
The computer name is SERVER-R2
```

As you can see, the \$phrase variable stays the same.

Another facet of this double-quotes trick is the PowerShell escape character. This character is the backtick (`), and on a U.S. keyboard it's located on one of the upper-left keys, usually below the Esc key and often on the same key as the tilde (~) character. The problem is that, in some fonts, it's practically indistinguishable from a single quote. In fact, we usually configure our shell to use the Consolas font, because that makes distinguishing the backtick easier than when using the Lucida Console or Raster fonts.

TRY IT NOW Click the control box in the upper-left corner of your PowerShell window and select Properties. On the Font tab, select the Consolas font as shown in figure 18.1. Click OK, and type a single quote and a backtick so you can see the difference between these characters. Figure 18.1 shows what it looks like on our system. Can't see the difference? We barely can, either, even when using a large font size. It's a tough distinction, but make sure you're comfortable distinguishing between these characters in whatever font face and size you select.

Let's look at what this escape character does. It removes whatever special meaning might be associated with the character after it, or in some cases, it adds special meaning to the following character. We have an example of this first use:

```
PS C:\> $computername = 'SERVER-R2'  
PS C:\> $phrase = "`$computername contains $computername"  
PS C:\> $phrase  
$computername contains SERVER-R2
```

When we assign the string to \$phrase, we use \$computername twice. The first time, we precede the dollar sign with a backtick. Doing this takes away the dollar sign's special meaning as a variable indicator and makes it a literal dollar sign. You can see in the preceding output, on the last line, that \$computername is stored in the variable. We don't use the backtick the second time, so \$computername is replaced with the contents of that variable.

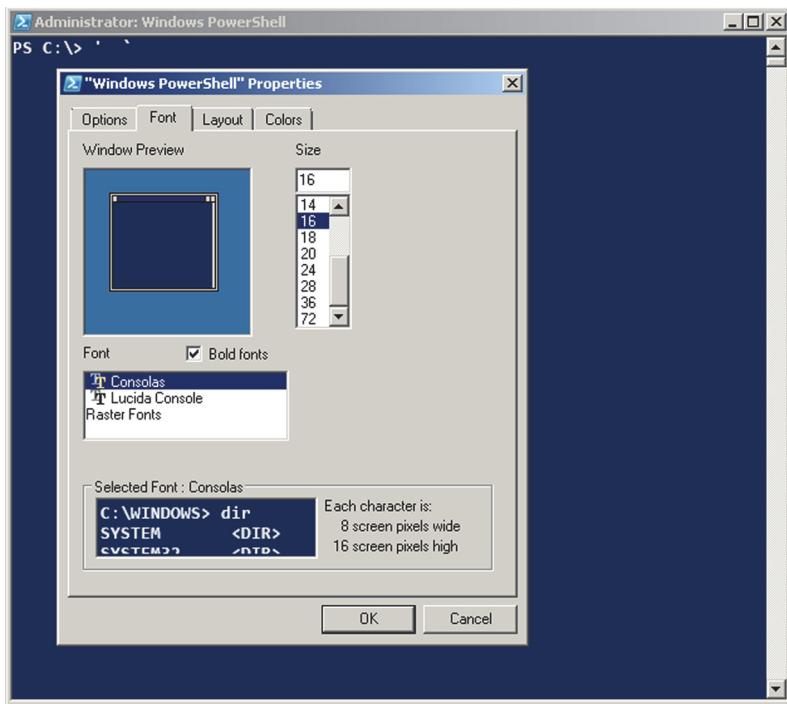

Figure 18.1 Setting a font that makes it easier to distinguish the backtick character from the single quote

Now let's look at an example of the second way a backtick can work:

```
PS C:\> $phrase = "`$computername`ncontains`n$computername"
PS C:\> $phrase
$computername
contains
SERVER-R2
```

Look carefully, and you'll notice we use `n twice in the phrase—once after the first \$computername and once after contains. In the example, the backtick adds a special meaning. Normally, n is a letter, but with the backtick in front of it, it becomes a carriage return and line feed (think n for new line).

Run help about_escape for more information, including a list of other special escape characters. You can, for example, use an escaped t to insert a tab, or an escaped a to make your computer beep (think a for alert).

18.4 Storing many objects in a variable

To this point, we've been working with variables that contain a single object, and those objects have all been simple values. We've worked directly with the objects themselves, rather than with their properties or methods. Let's now try putting a bunch of objects into a single variable.

One way to do this is to use a comma-separated list, because PowerShell recognizes those lists as collections of objects:

```
PS C:\> $computers = 'SERVER-R2', 'SERVER1', 'localhost'
PS C:\> $computers
SERVER-R2
SERVER1
localhost
```

Notice that we're careful in this example to put the commas outside the quotation marks. If we put them inside, we'd have a single object that includes commas and three computer names. With our method, we get three distinct objects, all of which are `String` types. As you can see, when we examine the contents of the variable, PowerShell displays each object on its own line.

18.4.1 Working with single objects in a variable

You can also access individual elements in the variable, one at a time. To do this, specify an index number for the object you want, in square brackets. The first object is always at index number 0, the second is at index number 1, and so forth. You can also use an index of -1 to access the last object, -2 for the next-to-last object, and so on. Here's an example:

```
PS C:\> $computers[0]
SERVER-R2
PS C:\> $computers[1]
SERVER1
PS C:\> $computers[-1]
localhost
PS C:\> $computers[-2]
SERVER1
```

The variable itself has a property that lets you see how many objects are in it:

```
PS C:\> $computers.Count
3
```

You can also access the properties and methods of the objects inside the variable as if they were properties and methods of the variable itself. This is easier to see, at first, with a variable that contains a single object:

```
PS C:\> $computername.length
9
PS C:\> $computername.toupper()
SERVER-R2
PS C:\> $computername.tolower()
server-r2
PS C:\> $computername.replace('R2','2008')
SERVER-2008
PS C:\> $computername
SERVER-R2
```

In this example, we're using the \$computername variable we created earlier in the chapter. As you may remember, that variable contains an object of the type `System.String`, and you should have seen the complete list of properties and methods of that type when you piped a string to `Get-Member` in section 18.2. We use the `Length` property, as well as the `ToUpper()`, `ToLower()`, and `Replace()` methods. In each case, we have to follow the method name with parentheses, even though neither `ToUpper()` nor `ToLower()` require any parameters inside those parentheses. Also, none of these methods change what is in the variable—you can see that on the last line. Instead, each method creates a new `String` based on the original one, as modified by the method.

18.4.2 Working with multiple objects in a variable

When a variable contains multiple objects, the steps can get trickier. Even if every object inside the variable is of the same type, as is the case with our `$computers` variable, PowerShell v2 didn't let you *call a method, or access a property, on multiple objects at the same time*. If you tried to do so, you got an error:

```
PS C:\> $computers.ToUpper()
Method invocation failed because [System.Object[]] doesn't contain a method named 'ToUpper'.
At line:1 char:19
+ $computers.ToUpper <<<< ()
+ CategoryInfo          : InvalidOperationException: (ToUpper:String) [], RunTimeException
+ FullyQualifiedErrorId : MethodNotFound
```

Instead, you'd have to specify which object within the variable you want, and then access a property or execute a method on that specific object:

```
PS C:\> $computers[0].ToLower()
server-r2
PS C:\> $computers[1].Replace('SERVER', 'CLIENT')
CLIENT1
```

Again, these methods are producing new strings, not changing the ones inside the variable. You can test that by examining the contents of the variable:

```
PS C:\> $computers
SERVER-R2
SERVER1
localhost
```

What if you want to change the contents of the variable? You assign a new value to one of the existing objects:

```
PS C:\> $computers[1] = $computers[1].Replace('SERVER', 'CLIENT')
PS C:\> $computers
SERVER-R2
CLIENT1
localhost
```

You can see in this example that we change the second object in the variable, rather than produce a new string. We point this out in case you’re dealing with computers that have only PowerShell v2 installed; the behavior has changed for v3, as you’ll see in a bit.

18.4.3 Other ways to work with multiple objects

We want to show you two other options for working with the properties and methods of a bunch of objects contained in a variable. The previous examples executed methods on only a single object within the variable. If you want to run the `ToLower()` method on every object within the variable, and store the results back into the variable, you do something like this:

```
PS C:\> $computers = $computers | ForEach-Object { $_.ToLower() }
PS C:\> $computers
server-r2
client1
localhost
```

This example is a bit complicated, so let’s break it down in figure 18.2. We start the pipeline with `$computers =`, which means the results of the pipeline will be stored in that variable. Those results overwrite whatever was in the variable previously.

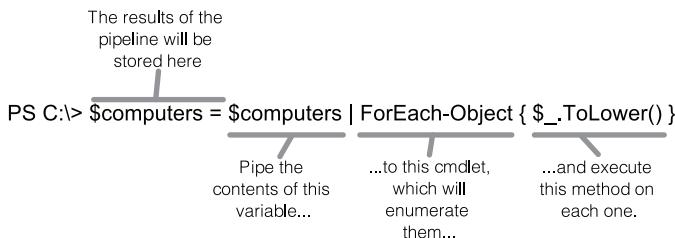

Figure 18.2 Using `ForEach-Object` to execute a method against each object contained within a variable

The pipeline begins with `$computers` being piped to `ForEach-Object`. The cmdlet enumerates each object in the pipeline (we have three computer names, which are `String` objects), and executes its script block for each. Within the script block, the `$_` placeholder contains one piped-in object at a time, and we’re executing the `ToLower()` method on each object. The new `String` objects produced by `ToLower()` are placed into the pipeline—and into the `$computers` variable.

You can do something similar with properties by using `Select-Object`. This example selects the `Length` property of each object you pipe to the cmdlet:

```
PS C:\> $computers | select-object length
```

Length

9
7
9

Because the property is numeric, PowerShell right-aligns the output.

18.4.4 Unrolling properties and methods in PowerShell v3

All this business of “you can’t access properties and methods when a variable contains multiple objects” proved to be extremely confusing for users of PowerShell v1 and v2. So confusing that, for v3, Microsoft made an important change, called *automatic unrolling*. You now *can* access properties and methods by using a variable that contains multiple objects:

```
$services = Get-Service
$services.Name
```

Under the hood, PowerShell “sees” that you’re trying to access a property in that example. It also sees that the collection in \$services doesn’t have a Name property—but that the individual objects within the collection do. So it implicitly enumerates, or unrolls, the objects, and grabs the Name property of each. This is equivalent to the following:

```
Get-Service | ForEach-Object { Write-Output $_.Name }
```

And also equivalent to this:

```
Get-Service | Select-Object -ExpandProperty Name
```

Which are the two ways you’d have had to do this in v1 and v2. The same thing works for methods:

```
$objects = Get-WmiObject -class Win32_Service -filter "name='BITS'"
$objects.ChangeStartMode('Disabled')
```

Just bear in mind that this is a PowerShell v3 feature. Don’t expect it to work this way on older versions of PowerShell.

18.5 More tricks with double quotes

We have another cool technique you can use with double quotes, which is a somewhat conceptual extension of the variable-replacement trick. Suppose, for example, that you’ve put a bunch of services into the \$service variable. Now you want to put only the name of the first one into a string:

```
PS C:\> $services = get-service
PS C:\> $firstname = "$services[0].name"
PS C:\> $firstname
AeLookupSvc ALG AllUserInstallAgent AppIDSvc Appinfo AppMgmt AudioEndpoint

inRm WlanSVC wlidSVC wmiApSVC WMPNetworkSVC WPSCSV WPDBusEnum wsCSVc WSear
ch WSService wuauserv wudfSVC WwanSVC [0].name
```

Err, oops. The `[` immediately after `$services` in the example isn't normally a legal character in a variable name, which causes PowerShell to try to replace `$services`. Doing this jams the name of every service into your string. The `[0].name` part isn't replaced at all.

The solution is to put all of that into an expression:

```
PS C:\> $services = get-service
PS C:\> $firstname = "The first name is $($services[0].name)"
PS C:\> $firstname
The first name is AeLookupSVC
```

Everything within `$()` is evaluated as a normal PowerShell command, and the result is placed into the string, replacing anything that's already there. Again, this works only in double quotes. This `$()` construct is called a *subexpression*.

We have another cool trick you can do in PowerShell v3. Sometimes you'll want to put something more complicated into a variable, and then display that variable's contents within quotation marks. In PowerShell v3, the shell is smart enough to enumerate all of the objects in a collection even when you refer to a single property or method, provided that all of the objects in the collection are of the same type. For example, we'll retrieve a list of services and put them into the `$service` variable, and then include only the services' names in double quotes:

```
PS C:\> $services = get-service
PS C:\> $var = "Service names are $services.name"
PS C:\> $var
Service names are AeLookupSVC ALG AllUserInstallAgent AppIDSvc Appinfo App
Mgmt AudioEndpointBuilder Audiosrv AxInstSV BDESVC BFE BITS BrokerInfrast

```

We truncated the preceding output to save space, but we hope you get the idea. Obviously, this might not be the exact output you're looking for, but between this technique and the subexpressions technique we showed you earlier in this section, you should be able to get exactly what you want.

18.6 Declaring a variable's type

So far we've put objects into variables and let PowerShell figure out what types of objects we were using. PowerShell doesn't care what kind of objects you put into the box. But you might care.

For example, suppose you have a variable that you expect to contain a number. You plan to do some arithmetic with that number, and you ask a user to input that number. Let's look at an example, which you can type directly into the command line:

```
PS C:\> $number = Read-Host "Enter a number"
Enter a number: 100
PS C:\> $number = $number * 10
PS C:\> $number
100100100100100100100100100100
```

TRY IT NOW We haven't showed you `Read-Host` yet—we're saving it for the next chapter—but its operation should be obvious if you follow along with this example.

What the heck? How can 100 multiplied by 10 be

100100100100100100100100100100? What crazy new math is that?

If you're sharp-eyed, you may have spotted what's happening. PowerShell doesn't treat our input as a number; it treats it as a string. Instead of multiplying 100 by 10, PowerShell *duplicates the string "100" ten times*. The result then is the string 100, listed ten times in a row. Oops.

We can verify that the shell is in fact treating the input as a string:

```
PS C:\> $number = Read-Host "Enter a number"
Enter a number: 100
PS C:\> $number | gm
```

Name	MemberType	Definition
Clone	Method	System.Object Clone()
CompareTo	Method	int CompareTo(System.Object value)
Contains	Method	bool Contains(string value)

Yep, piping `$number` to `Gm` confirms that the shell sees it as a `System.String`, not a `System.Int32`. There are a couple of ways to deal with this problem, and we'll show you the easiest one.

First, we tell the shell that the `$number` variable should contain an integer, which will force the shell to try to convert any input to a real number. We do that in the following example by specifying the desired data type, `int`, in square brackets immediately prior to the variable's first use:

```
PS C:\> [int]$number = Read-Host "Enter a number"
Enter a number: 100
PS C:\> $number | gm
 TypeName: System.Int32
Name      MemberType  Definition
----      ----       -----
CompareTo Method     int CompareTo(System.Object value), int CompareT...
Equals    Method     bool Equals(System.Object obj), bool Equals(int ...
GetHashCode Method     int GetHashCode()
GetType   Method     type GetType()
GetTypeCode Method     System.TypeCode GetTypeCode()
ToString   Method     string ToString(), string ToString(string format...
PS C:\> $number = $number * 10
PS C:\> $number
1000
```

1 Force variable to [int]
2 Confirm that variable is Int32
3 Variable was treated as number

In this example, we use `[int]` to force `$number` to contain only integers **1**. After entering our input, we pipe `$number` to `Gm` to confirm that it's indeed an integer, and not a string **2**. At the end, you can see that the variable is treated as a number and real multiplication takes place **3**.

Another benefit to using this technique is that the shell will throw an error if it can't convert the input into a number, because `$number` is capable of storing only integers:

```
PS C:\> [int]$number = Read-Host "Enter a number"
Enter a number: Hello
Cannot convert value "Hello" to type "System.Int32". Error: "Input string
was not in a correct format."
At line:1 char:13
+ [int]$number <<<= Read-Host "Enter a number"
+ CategoryInfo          : MetadataError: (:) [], ArgumentTransformati
onMetadataException
+ FullyQualifiedErrorId : RuntimeException
```

This is a great example of how to prevent problems down the line, because you're assured that `$number` will contain the exact type of data you expect it to.

You can use many object types in place of `[int]`, but the following list includes some of the ones you'll most commonly use:

- `[int]`—Integer numbers
- `[single]` and `[double]`—Single-precision and double-precision floating numbers (numbers with a decimal portion)
- `[string]`—A string of characters
- `[char]`—Exactly one character (as in, `[char]$c = 'X'`)
- `[xml]`—An XML document; whatever string you assign to this will be parsed to make sure it contains valid XML markup (for example, `[xml]$doc = Get-Content MyXML.xml`)
- `[adsi]`—An Active Directory Service Interfaces (ADSI) query; the shell will execute the query and place the resulting object or objects into the variable (such as `[adsi]$user = "WinNT:\MYDOMAIN\Administrator,user"`)

Specifying an object type for a variable is a great way to prevent certain tricky logic errors in more-complex scripts. As the following example shows, once you specify the object type, PowerShell enforces it until you explicitly retype the variable:

```
PS C:\> [int]$x = 5          ← ① Declares $x as integer
PS C:\> $x = 'Hello'
Cannot convert value "Hello" to type "System.Int32". Error: "Input string
was not in a correct format."
At line:1 char:3
+ $x <<<= 'Hello'
+ CategoryInfo          : MetadataError: (:) [], ArgumentTransformati
onMetadataException
+ FullyQualifiedErrorId : RuntimeException
PS C:\> [string]$x = 'Hello'   ← ② Creates error by putting
PS C:\> $x | gm               string into $x
                           ← ③ Retypes $x
                           as string
                           ← ④ Confirms new
                           type of $x
   TypeName: System.String
   Name          MemberType      Definition
   ----          -----          -----
   Clone         Method          System.Object Clone()
   CompareTo    Method          int CompareTo(System.Object valu...
```

In this example, you can see that we start by declaring \$x as an integer ①, and placing an integer into it. When we try to put a string into it ②, PowerShell throws an error because it can't convert that particular string into a number. Later we retype \$x as a string, and we're able to put a string into it ③. We confirm that by piping the variable to `Gm` and checking its type name ④.

18.7 Commands for working with variables

We've started to use variables at this point, without formally declaring our intention to do so. PowerShell doesn't require advanced variable declaration, and you can't force it to make a declaration. (VBScript folks who are looking for something like `Option Explicit` will be disappointed; PowerShell has something called `Set-StrictMode`, but it isn't exactly the same thing.) But the shell does include the following commands for working with variables:

- `New-Variable`
- `Set-Variable`
- `Remove-Variable`
- `Get-Variable`
- `Clear-Variable`

You don't need to use any of these except perhaps `Remove-Variable`, which is useful for permanently deleting a variable (you can also use the `Del` command within the `VARIABLE:` drive to delete a variable). You can perform every other function—creating new variables, reading variables, and setting variables—by using the ad hoc syntax we've used up to this point in the chapter; using these cmdlets offers no specific advantages in most cases.

If you do decide to use these cmdlets, you give your variable name to the cmdlets' `-name` parameters. This is *only the variable name*—it doesn't include the dollar sign. The one time you might want to use one of these cmdlets is when working with something called an *out-of-scope* variable. Messing with out-of-scope variables is a poor practice, and we don't cover out-of-scope variables (or much more on scope) in this book, but you can run `help about_scope` in the shell to learn more.

18.8 Variable best practices

We've mentioned most of these practices already, but this is a good time to quickly review them:

- Keep variable names meaningful but succinct. Whereas `$computername` is a great variable name because it's clear and concise, `$c` is a poor name, because what it contains isn't clear. The variable name `$computer_to_query_for_data` is a bit long for our tastes. Sure, it's meaningful, but do you want to type that over and over?
- Don't use spaces in variable names. We know you can, but it's ugly syntax.
- If a variable contains only one kind of object, declare that when you first use the variable. This can help prevent confusing logic errors, and if you're working in a commercial script development environment (PowerShell Studio is the example we're thinking of), the editor software can provide code-hinting features when you tell it the type of object that a variable will contain.

18.9 Common points of confusion

The biggest single point of confusion we see new students struggle with is the variable name. We hope we've done a good job of explaining it in this chapter, but always remember that the dollar sign *isn't part of the variable's name*. It's a cue to the shell that you want to access the *contents* of a variable; what follows the dollar sign is taken as the variable's name.

The shell has two parsing rules that let it capture the variable name:

- If the character immediately after the dollar sign is a letter, number, or underscore, the variable name consists of all the characters following the dollar sign, up to the next white space (which might be a space, tab, or carriage return).
- If the character immediately after the dollar sign is an opening curly brace, `{`, the variable name consists of everything after that curly brace up to, but not including, the closing curly brace, `}`.

18.10 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

Flip back to chapter 15 and refresh your memory on working with background jobs. Then, at the command line, do the following:

- 1 Create a background job that queries the `Win32_BIOS` information from two computers (use `localhost` twice if you have only one computer to experiment with).
- 2 When the job finishes running, receive the results of the job into a variable.
- 3 Display the contents of that variable.
- 4 Export the variable's contents to a CliXML file.

18.11 Further exploration

Take a few moments and skim through some of the previous chapters in this book. Given that variables are primarily designed to store something you might use more than once, can you find a use for variables in our topics in previous chapters?

For example, in chapter 13 you learned to create connections to remote computers. In that chapter, you created, used, and closed a connection more or less in one step; wouldn't it be useful to create the connection, store it in a variable, and use it for several commands? That's only one instance of where variables can come in handy (and we'll show you how to do that in chapter 20). See if you can find any more examples.

18.12 Lab answers

```
1 PS C:\> invoke-command {get-wmiobject win32_bios} -computername  
localhost,$env:computername -asjob  
2 PS C:\>$results=Receive-Job 4 -keep  
3 PS C:\>$results  
4 PS C:\>$results | export-clixml bios.xml
```

19

Input and output

To this point in the book, we've primarily been relying on PowerShell's native ability to output tables and lists. As you start to combine commands into more-complex scripts, you'll probably want to gain more precise control over what's displayed. You may also need to prompt a user for input. In this chapter, you'll learn how to collect that input, and how to display whatever output you might desire.

We want to point out, however, that the contents of this chapter are useful only for scripts that interact with human eyeballs and fingertips. For scripts that run unattended, these aren't appropriate techniques, because there won't be a human being around to interact with.

19.1 Prompting for, and displaying, information

The way PowerShell displays and prompts for information depends on how it's being run. You see, PowerShell is built as a kind of under-the-hood engine.

What you interact with is called a *host application*. The command-line console you see when running PowerShell.exe is often called the *console host*. The graphical PowerShell ISE is usually called the *ISE host or the graphical host*. Other non-Microsoft applications can host the shell's engine as well. You interact with the hosting application, and it passes your commands through to the engine. The hosting application displays the results that the engine produces.

Figure 19.1 illustrates the relationship between the engine and the various hosting applications. Each hosting application is responsible for physically displaying any output the engine produces, and for physically collecting any input the engine requests. That means PowerShell can display output and collect input in different ways. In fact, the console host and ISE use different methods for collecting input:

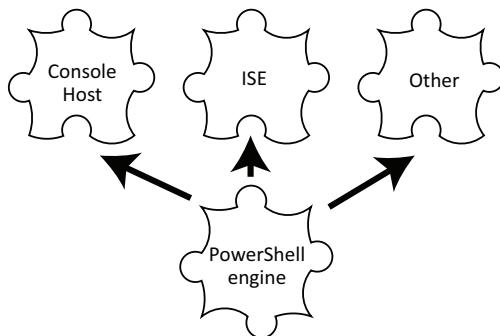

Figure 19.1 Various applications are capable of hosting the PowerShell engine.

The console host presents a text prompt within the command line, but the ISE produces a pop-up dialog box with a text-entry area and an OK button.

We want to point out these differences because it can sometimes be confusing to newcomers. Why would one command behave one way in the command-line window but behave completely differently in the ISE? It's because the way in which you interact with the shell is determined by the hosting application, and not by PowerShell itself. The commands we're about to show you exhibit slightly different behavior depending on where you run them.

19.2 Read-Host

PowerShell's `Read-Host` cmdlet is designed to display a text prompt and then collect text input from the user. Because you saw us use this for the first time in the previous chapter, the syntax may seem familiar:

```
PS C:\> read-host "Enter a computer name"
Enter a computer name: SERVER-R2
SERVER-R2
```

This example highlights two important facts about the cmdlet:

- A colon is added to the end of the prompt.
- Whatever the user types is returned as the result of the command (technically, it's placed into the pipeline).

You'll often capture the input into a variable, which looks like this:

```
PS C:\> $computername = read-host "Enter a computer name"
Enter a computer name: SERVER-R2
```

TRY IT NOW Time to start following along. At this point, you should have a valid computer name in the `$computername` variable. Don't use SERVER-R2 unless that's the name of the computer you're working on.

As we mentioned earlier, the PowerShell v2 ISE displays a dialog box, rather than prompting directly within the command line, as shown in figure 19.2. Each hosting

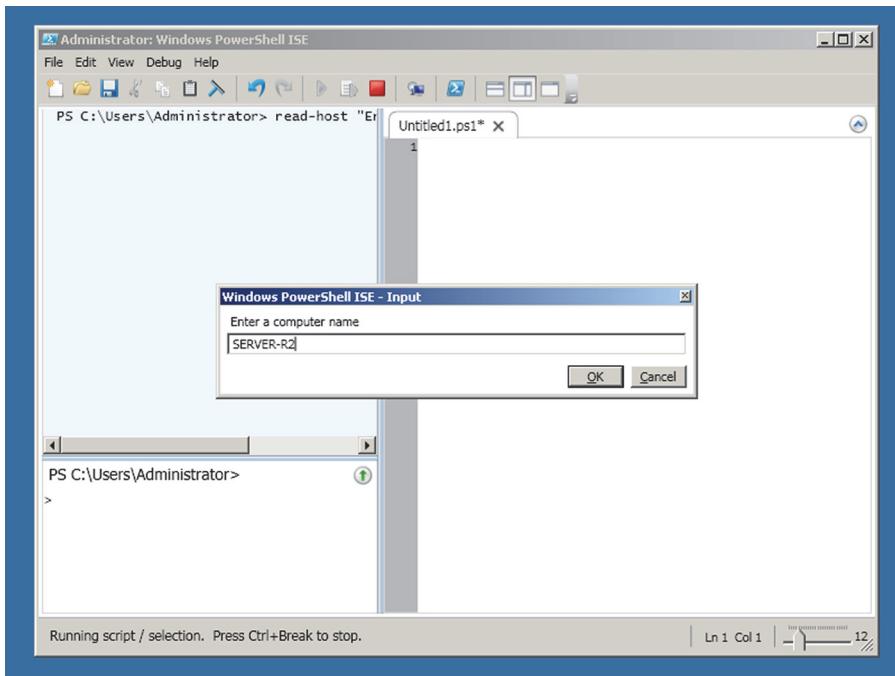

Figure 19.2 The v2 ISE displays a dialog box for `Read-Host`.

application—including script editors such as PowerGUI, PowerShell Plus, or PowerShell Studio—has its own way of implementing `Read-Host`. Note that the PowerShell v3 (and later) ISE, which uses a simpler two-pane layout than the v2 ISE, displays a command-line prompt much like the regular console window.

There isn't much else to say about `Read-Host`: It's a useful cmdlet, but not a particularly exciting one. In fact, after introducing `Read-Host` in most classes, someone typically asks us, “Is there a way to always display a graphical input box?” Many administrators want to deploy scripts to their users, and they don't want users to have to enter information into a command-line interface (it isn't “Windows-like,” after all). The answer we give is yes, but it isn't straightforward. The final result is shown in figure 19.3.

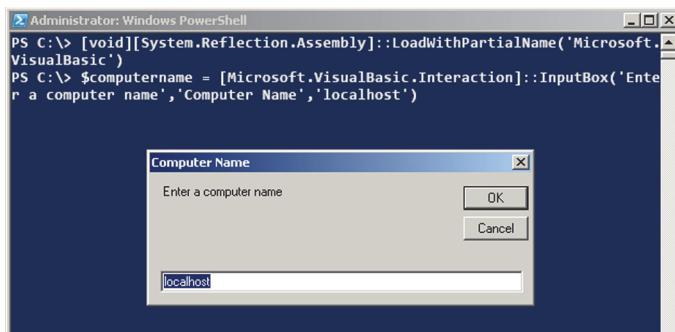

Figure 19.3 Creating a graphical input box in Windows PowerShell

To create the graphical input box, you'll have to dive into the .NET Framework itself. Start with the following command:

```
PS C:\> [void] [System.Reflection.Assembly]::LoadWithPartialName('Microsoft  
➥.VisualBasic')
```

You have to do this only once in a given shell session, but it doesn't hurt to run the command a second time.

This command loads a portion of the .NET Framework, Microsoft.VisualBasic, which PowerShell doesn't automatically load. This portion of the framework contains most of the Visual Basic-centric framework elements, including things like graphical input boxes.

Let's look at what the command is doing:

- The [void] part is converting the result of the command into the void data type. You learned how to do this kind of conversion with integers in the previous chapter; the void data type is a special type that means "throw the result away." We don't want to see the result of this command, so we convert the result to void. Another way to do the same thing would be to pipe the result to Out-Null.
- Next, we're accessing the System.Reflection.Assembly type, which represents our application (which is PowerShell). We've enclosed the type name in square brackets, as if we were declaring a variable to be of that type. But rather than declaring a variable, we're using two colons to access a *static method* of the type. Static methods exist without us having to create an instance of the type.
- The static method we're using is LoadWithPartialName(), which accepts the name of the framework component we want to load.

If all of that is as clear as mud, don't worry; you can use the command as is, without needing to understand how it works. Once the right bits of the framework are loaded, you can use them as follows:

```
PS C:\> $computername = [Microsoft.VisualBasic.Interaction]::InputBox('Enter  
➥ a computer name', 'Computer Name', 'localhost')
```

In this example, we use a static method again, this time from the Microsoft .Visual-Basic.Interaction type, which we loaded into memory with the previous command. Again, if the "static method" stuff doesn't make sense, don't worry—use this command as is.

The three bits you can change are the parameters of the InputBox() method:

- The first parameter is the text for your prompt.
- The second parameter is the title for the prompt's dialog box.
- The third parameter, which can be left blank or omitted entirely, is the default value that you want prefilled in the input box.

Using Read-Host may be less complicated than following the steps in the previous example, but if you insist on a dialog box, this is how you create one.

19.3 Write-Host

Now that you can collect input, you'll want some way of displaying output. The `Write-Host` cmdlet is one way. It's not always the best way, but it's available to you, and it's important that you understand how it works.

As figure 19.4 illustrates, `Write-Host` runs in the pipeline like any other cmdlet, but it doesn't place anything into the pipeline. Instead, it writes directly to the hosting application's screen. Because it does that, it's able to use alternate foreground and background colors, through its `-foregroundColor` and `-backgroundColor` command-line parameters.

```
PS C:\> write-host "COLORFUL!" -fore yellow -back magenta
COLORFUL!
```

TRY IT NOW You'll want to run this command yourself to see the colorful results.

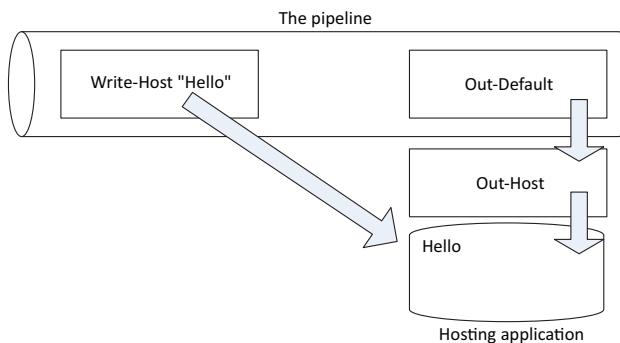

Figure 19.4 `Write-Host` bypasses the pipeline and writes directly to the hosting application's display.

NOTE Not every application that hosts PowerShell supports alternate text colors, and not every application supports the full set of colors. When you attempt to set colors in such an application, it will usually ignore any colors it doesn't like or can't display. That's one reason we tend to avoid relying on special colors at all.

You should use `Write-Host` only when you need to display a specific message, perhaps using color to draw attention to it. But this isn't the appropriate way to produce normal output from a script or a command. Also keep in mind that anything written to the screen by a `-Host` command *can't be captured*. If you run a script remotely, or unattended, the `-Host` commands won't work as you might think. As we wrote at the start of this chapter, `-Host` commands are only for interacting directly with local human beings—which should be a very limited subset of the tasks you perform in PowerShell.

For example, you should never use `Write-Host` to manually format a table; you can find better ways to produce the output, using techniques that enable PowerShell itself to handle the formatting. We won't dive into those techniques in this book, because they belong more in the realm of heavy-duty scripting and toolmaking. However, you

can check out *Learn PowerShell Toolmaking in a Month of Lunches* (Manning, 2012) for full coverage of those output techniques. Write-Host is also not the best way to produce error messages, warnings, debugging messages, and so on—again, you can find more specific ways to do those things, and we'll cover those in this chapter. You probably won't use Write-Host much, if you're using the shell correctly.

NOTE We often see people using Write-Host to display what we call “warm and fuzzy” messages—things like “now connecting to SERVER2,” “testing for folder,” and so on. Don’t. The more appropriate way to display those messages is with the Write-Verbose cmdlet.

Above and beyond

We'll dive into Write-Verbose and the other Write cmdlets a bit more in chapter 22. But if you try Write-Verbose now, you might be disappointed to discover that it doesn't produce any output. Well, not by default.

If you plan to use Write cmdlets, the trick is to turn them on first. For example, set \$VerbosePreference="Continue" to enable Write-Verbose, and \$VerbosePreference="SilentlyContinue" to suppress its output. You'll find similar “preference” variables for Write-Debug (\$DebugPreference) and Write-Warning (\$WarningPreference).

Chapter 22 includes an even cooler way to use Write-Verbose.

It may seem *much* easier to use Write-Host, and if you want to, you can. But keep in mind that by using the other cmdlets, such as Write-Verbose, you're going to be following PowerShell's own patterns more closely, resulting in a more consistent experience.

19.4 Write-Output

Unlike Write-Host, Write-Output can send objects into the pipeline. Because it isn't writing directly to the display, it doesn't permit you to specify alternative colors or anything. In fact, Write-Output (or its alias, Write) isn't technically designed to display output at all. As we said, it sends objects into the pipeline—it's the pipeline itself that eventually displays those objects. Figure 19.5 illustrates how this works.

Refer to chapter 10 for a quick review of how objects go from the pipeline to the screen. Let's look at the basic process:

- 1 Write-Output puts the String object Hello into the pipeline.
- 2 Because nothing else is in the pipeline, Hello travels to the end of the pipeline, where Out-Default always sits.
- 3 Out-Default passes the object to Out-Host.
- 4 Out-Host asks PowerShell's formatting system to format the object. Because in this example it's a simple String, the formatting system returns the text of the string.
- 5 Out-Host places the formatted result onto the screen.

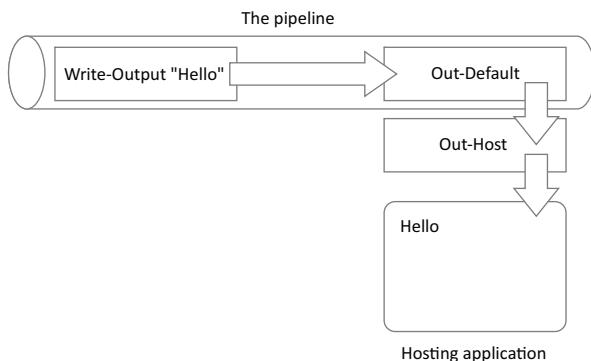

Figure 19.5 `Write-Output` puts objects into the pipeline, which in some cases eventually results in those objects being displayed.

The results are similar to what you'd get using `Write-Host`, but the object takes a different path to get there. That path is important, because the pipeline could contain other things. For example, consider the following command (which you're welcome to try):

```
PS C:\> write-output "Hello" | where-object { $_.length -gt 10 }
```

You don't see any output from this command, and figure 19.6 illustrates why. `Hello` is placed into the pipeline. But before it gets to `Out-Default`, it has to pass through `Where-Object`, which filters out anything having a `Length` property of less than or equal to 10, which in this case includes our poor `Hello`. Our `Hello` gets dropped out of the pipeline, and because there's nothing left in the pipeline for `Out-Default`, there's nothing to pass to `Out-Host`, so nothing is displayed. Contrast that command with the following one:

```
PS C:\> write-host "Hello" | where-object { $_.length -gt 10 }
Hello
```

All we've done is replace `Write-Output` with `Write-Host`. This time, `Hello` goes directly to the screen, not into the pipeline. `Where-Object` has no input, and produces

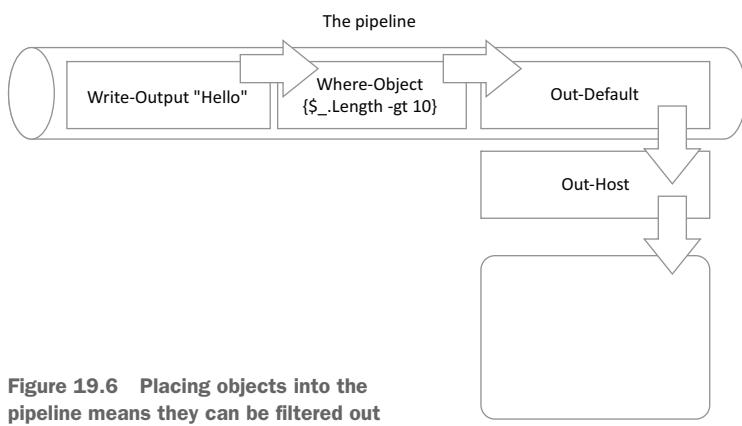

Figure 19.6 Placing objects into the pipeline means they can be filtered out before they're displayed.

Hosting application

no output, so nothing is displayed by `Out-Default` and `Out-Host`. But because `Hello` has been written directly to the screen, we see it anyway.

`Write-Output` may seem new, but it turns out you've been using it all along. It's the shell's default cmdlet. When you tell the shell to do something that isn't a command, the shell passes whatever you typed to `Write-Output` behind the scenes.

19.5 Other ways to write

PowerShell has a few other ways to produce output. None of these write to the pipeline as `Write-Output` does; they work a bit more like `Write-Host`. But all of them produce output in a way that can be suppressed.

The shell comes with built-in configuration variables for each of these alternative output methods. When the configuration variable is set to `Continue`, the commands we're about to show you do indeed produce output. When the configuration variable is set to `SilentlyContinue`, the associated output command produces nothing. Table 19.1 contains the list of cmdlets.

Table 19.1 Alternative output cmdlets

Cmdlet	Purpose	Configuration variable
<code>Write-Warning</code>	Displays warning text, in yellow by default, and preceded by the label <code>WARNING:</code>	<code>\$WarningPreference</code> (<code>Continue</code> by default)
<code>Write-Verbose</code>	Displays additional informative text, in yellow by default, and preceded by the label <code>VERBOSE:</code>	<code>\$VerbosePreference</code> (<code>SilentlyContinue</code> by default)
<code>Write-Debug</code>	Displays debugging text, in yellow by default, and preceded by the label <code>DEBUG:</code>	<code>\$DebugPreference</code> (<code>SilentlyContinue</code> by default)
<code>Write-Error</code>	Produces an error message	<code>\$ErrorActionPreference</code> (<code>Continue</code> by default)

NOTE PowerShell v5 introduced a new command, `Write-Information`. This writes to a unique, structured Information stream in the shell, letting you write both structured data and informational messages. In PowerShell v5 and later, `Write-Host` uses `Write-Information` under the hood. Read more about the new command at <https://technet.microsoft.com/en-us/library/dn998020.aspx>.

`Write-Error` works a bit differently because it writes an error to PowerShell's error stream.

PowerShell also has a `Write-Progress` cmdlet that can display progress bars, but it works entirely differently. Feel free to read its help for more information and for examples; we don't cover it in this book.

To use any of these cmdlets, first make sure that its associated configuration variable is set to `Continue`. (If it's set to `SilentlyContinue`, which is the default for a couple of them, you won't see any output at all.) Then use the cmdlet to output a message.

NOTE Some PowerShell hosting applications may display the output from these cmdlets in a different location. In PowerShell Studio from SAPIEN, for example, debugging text is written to a different output pane than the script's main output, allowing the debug text to be more easily separated for analysis. We don't dive into debugging in this book, but you can read more about the cmdlet in PowerShell's help system if you're interested.

19.6 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

`Write-Host` and `Write-Output` can be a bit tricky to work with. See how many of these tasks you can complete, and if you get stuck, it's OK to peek at the sample answers available at the end of this chapter.

- 1 Use `Write-Output` to display the result of 100 multiplied by 10.
- 2 Use `Write-Host` to display the result of 100 multiplied by 10.
- 3 Prompt the user to enter a name, and then display that name in yellow text.
- 4 Prompt the user to enter a name, and then display that name only if it's longer than five characters. Do this all with a single PowerShell expression—don't use a variable.

That's all for this lab. Because these cmdlets are all straightforward, we want you to spend more time experimenting with them on your own. Be sure to do that—we'll offer some ideas in the next section.

TRY IT NOW After you've completed this lab, try completing review lab 3, which you'll find in the appendix of this book.

19.7 Further exploration

Spend some time getting comfortable with all of the cmdlets in this chapter. Make sure you can display verbose output, accept input, and even display a graphical input box. You'll be using the commands from this chapter often from here on out, so you should read their help files and even jot down quick syntax reminders for future reference.

19.8 Lab answers

- 1 `write-output (100*10)`
or simply type the formula: `100*10`
- 2 Any of these approaches work:

```
$a=100*10
Write-Host $a
Write-Host "The value of 100*10 is $a"
Write-Host (100*10)
```
- 3 `$name=Read-Host "Enter a name"` `Write-host $name -ForegroundColor Yellow`
- 4 `Read-Host "Enter a name" | where {$_.length -gt 5}`

Sessions: remote control with less work

In chapter 13, we introduced you to PowerShell’s remoting features. In that chapter, you used two primary cmdlets—`Invoke-Command` and `Enter-PSSession`—to access both one-to-many and one-to-one remote control. Those two cmdlets work by creating a new remoting connection, doing whatever work you specify, and then closing that connection.

There’s nothing wrong with that approach, but it can be tiring to have to continually specify computer names, credentials, alternative port numbers, and so on. In this chapter, you’ll look at an easier, more reusable way to tackle remoting. You’ll also learn about a third way to use remoting that also comes in handy.

20.1 Making PowerShell remoting a bit easier

Anytime you need to connect to a remote computer, using either `Invoke-Command` or `Enter-PSSession`, you have to at least specify the computer’s name (or names, if you’re invoking a command on multiple computers). Depending on your environment, you may also have to specify alternative credentials, which means being prompted for a password. You might also need to specify alternative ports or authentication mechanisms, depending upon how your organization has configured remoting.

None of that is difficult to specify, but it can be tedious to have to repeat the process again and again. Fortunately, we know of a better way: reusable sessions.

20.2 Creating and using reusable sessions

A *session* is a persistent connection between your copy of PowerShell and a remote copy of PowerShell. When the session is active, both your computer and the remote machine devote a small amount of memory and processor time toward maintaining the connection, although there's little network traffic involved in the connection. PowerShell maintains a list of all the sessions you've opened, and you can use those sessions to invoke commands or to enter a remote shell.

To create a new session, use the `New-PSSession` cmdlet. Specify the computer name (or names), and, if necessary, specify an alternative username, port, authentication mechanism, and so forth. The result will be a session object, which is stored in PowerShell's memory:

```
PS C:\> new-pssession -computername server-r2,server17,dcs5
```

To retrieve those sessions, run `Get-PSSession`:

```
PS C:\> get-pssession
```

Although that works, we prefer to create the sessions and then immediately store them in a variable. For example, Don has three IIS-based web servers that he routinely reconfigures by using `Invoke-Command`. To make the process easier, he stores those sessions in a specific variable:

```
PS C:\> $iis_servers = new-pssession -comp web1,web2,web3  
➥ -credential WebAdmin
```

Never forget that those sessions consume resources. If you close the shell, they'll close automatically, but if you're not actively using them, it's a good idea to manually close them even if you're planning to continue using the shell for other tasks.

To close a session, use the `Remove-PSSession` cmdlet. For example, to close only the IIS sessions, use the following command:

```
PS C:\> $iis_servers | remove-pssession
```

Or, if you want to close all open sessions, use this next command:

```
PS C:\> get-pssession | remove-pssession
```

That's easy enough.

But once you get some sessions up and running, what will you do with them? For the next couple of sections, we'll assume you've created a variable named `$sessions` that contains at least two sessions. We'll use `localhost` and `SERVER-R2` (you should specify your own computer names). Using `localhost` isn't cheating: PowerShell starts up a real remoting session with another copy of itself. Keep in mind that this will work only if you've enabled remoting on all computers to which you're connected, so revisit chapter 13 if you haven't enabled remoting.

TRY IT NOW Start to follow along and run these commands, and be sure to use valid computer names. If you have only one computer, use both its name and localhost.

Above and beyond

There's a cool syntax that allows you to create multiple sessions with one command and have each session assigned to a unique variable (instead of having them all lumped into one variable, as we previously did):

```
$s_server1,$s_server2 = New-PSSession -computer server-r2,dc01
```

This syntax puts the session for SERVER-R2 into \$s_server1, and the session for DC01 into \$s_server2, which can make it easier to use those sessions independently.

But use caution: We've seen instances where the sessions aren't created in exactly the order you specify, so \$s_server1 might end up containing the session for DC01 instead of SERVER-R2. You can display the variable's contents to see which computer it's connected to.

Here's how we'll get our sessions up and running:

```
PS C:\> $sessions = New-PSSession -comp SERVER-R2,localhost
```

Bear in mind that we've already enabled remoting on these computers and that they're all in the same domain. Revisit chapter 13 if you'd like a refresher on how to enable remoting.

20.3 Using sessions with Enter-PSSession

As we hope you recall from chapter 13, the Enter-PSSession cmdlet is the one you use to engage a one-to-one remote interactive shell with a single remote computer. Rather than specifying a computer name with the cmdlet, you can specify a single session object. Because our \$sessions variable has two session objects, we must specify one of them using an index (which you first learned to do in chapter 18):

```
PS C:\> enter-pssession -session $sessions [0]
[server-r2]: PS C:\Users\Administrator\Documents>
```

You can see that our prompt changes to indicate that we're now controlling a remote computer. Exit-PSSession returns us to the local prompt, but the session remains open for additional use:

```
[server-r2]: PS C:\Users\Administrator\Documents> exit-pssession
PS C:\>
```

You might have a tough time remembering which index number goes with which computer. In that case, you can take advantage of the properties of a session object. For example, when we pipe \$sessions to Get-Member, we get the following output:

```
PS C:\> $sessions | gm

TypeName: System.Management.Automation.Runspaces.PSSession
Name          MemberType   Definition
----          -----      -----
Equals        Method      bool Equals(System.Object obj)
GetHashCode   Method      int GetHashCode()
GetType       Method      type GetType()
ToString      Method      string ToString()
ApplicationPrivateData Property  System.Management.Automation.PSP...
Availability  Property  System.Management.Automation.Run...
ComputerName  Property  System.String ComputerName {get;}
ConfigurationName Property  System.String ConfigurationName {...
Id           Property  System.Int32 Id {get;}
InstanceId   Property  System.Guid InstanceId {get;}
Name         Property  System.String Name {get;set;}
Runspace     Property  System.Management.Automation.Run...
State        ScriptProperty System.Object State {get=$this.Ru...
```

In the preceding output, you can see that the session object has a ComputerName property, which means you can filter for that session:

```
PS C:\> enter-pssession -session ($sessions |
➥where { $_.computername -eq 'server-r2' })
[server-r2]: PS C:\Users\Administrator\Documents>
```

That's awkward syntax, though. If you need to use a single session from a variable, and you can't remember which index number is which, it might be easier to forget about using the variable.

Even though you stored your session objects in the variable, they're also still stored in PowerShell's master list of open sessions. You can access them by using Get-PSSession:

```
PS C:\> enter-pssession -session (get-pssession -computer server-r2)
```

Get-PSSession retrieves the session having the computer named SERVER-R2 and passes it to the -session parameter of Enter-PSSession.

When we first figured out that technique, we were impressed, but it also led us to dig a bit deeper. We pulled up the full help for Enter-PSSession and read more closely about the -session parameter. Here's what we looked at:

```
-Session <PSSession>
    Specifies a Windows PowerShell session (PSSession) to use for the
    interactive session. This parameter takes a session object. You ca
    n also use the Name, InstanceID, or ID parameters to specify a PSS
    ession.
    Enter a variable that contains a session object or a command that
    creates or gets a session object, such as a New-PSSession or Get-P
    SSSession command. You can also pipe a session object to Enter-PSSe
    ssion. You can submit only one PSSession with this parameter. If y
    ou enter a variable that contains more than one PSSession, the com
    mand fails.
    When you use Exit-PSSession or the EXIT keyword, the interactive s
    ession ends, but the PSSession that you created remains open and a
    vailable for use.
```

```

Required?          false
Position?         1
Default value
Accept pipeline input?    true (ByValue, ByPropertyName)
Accept wildcard characters? True

```

If you think back to chapter 9, you'll find that pipeline input information near the end of the help interesting. It tells us that the `-session` parameter can accept a `PSSession` object from the pipeline. We know that `Get-PSSession` produces `PSSession` objects, so the following syntax should also work:

```
PS C:\> Get-PSSession -ComputerName SERVER-R2 | Enter-PSSession
[server-r2]: PS C:\Users\Administrator\Documents>
```

And it does work. We think that's a much more elegant way to retrieve a single session, even if you've stored them all in a variable.

TIP Storing sessions in a variable is fine as a convenience. But keep in mind that PowerShell is already storing a list of all open sessions; having them in a variable is useful only when you want to refer to a bunch of sessions at once, as you'll see in the next section.

20.4 Using sessions with Invoke-Command

Sessions show their usefulness with `Invoke-Command`, which you'll remember you use to send a command (or an entire script) to multiple remote computers in parallel. With our sessions in a `$sessions` variable, we can easily target them all with the following command:

```
PS C:\> invoke-command -command { get-wmiobject -class win32_process }
➥ -session $sessions
```

Notice that we're sending a `Get-WmiObject` command to the remote computers. We could have chosen to use `Get-WmiObject`'s own `-computername` parameter, but we didn't do so for the following four reasons:

- Remoting works over a single, predefined port; WMI doesn't. Remoting is therefore easier to use with firewalled computers, because it's easier to make the necessary firewall exceptions. Microsoft's Windows Firewall provides a specific exception for WMI that includes the stateful inspection necessary to make WMI's random port selection (called *endpoint mapping*) work properly, but it can be difficult to manage with some third-party firewall products. With remoting, it's an easy, single port.
- Pulling all of the processes can be labor intensive. Using the `Invoke-Command` cmdlet gets each computer to do its own share of the work and send the results back.
- Remoting operates in parallel, contacting up to 32 computers at once by default. WMI works sequentially with only one computer at a time.
- We can't use our predefined sessions with `Get-WmiObject`, but we can use them with `Invoke-Command`.

NOTE The new CIM cmdlets (such as `Get-CimInstance`) in PowerShell v3 don't have a `-computerName` parameter as `Get-WmiObject` does. These new cmdlets are designed for you to send via `Invoke-Command` when you want to run them against a remote computer.

The `-session` parameter of `Invoke-Command` can also be fed with a parenthetical command, much as we've done with computer names in previous chapters. For example, the following sends a command to every session connected to a computer whose name is listed:

```
PS C:\> invoke-command -command { get-wmiobject -class win32_process }
➥-session (get-pssession -comp server1,server2,server3)
```

You might expect that `Invoke-Command` would be able to receive session objects from the pipeline, as you know `Enter-PSSession` can. But a glance at the full help for `Invoke-Command` shows that it can't do that particular pipeline trick. Too bad, but the preceding example of using a parenthetical expression provides the same functionality without too difficult a syntax.

20.5 Implicit remoting: importing a session

Implicit remoting, for us, is one of the coolest and most useful—possibly *the* coolest and *the* most useful—feature a command-line interface has ever had, on any operating system, ever. And unfortunately, it's barely documented in PowerShell. Sure, the necessary commands are well-documented, but how they come together to form this incredible capability isn't mentioned. Fortunately, we have you covered on this one.

Let's review the scenario: You already know that Microsoft is shipping more and more modules and snap-ins with Windows and other products, but sometimes you can't install those modules and snap-ins on your local computer for one reason or another. The `ActiveDirectory` module, which shipped for the first time with Windows Server 2008 R2, is a perfect example: It exists only on Windows Server 2008 R2 and on Windows 7 machines that have the Remote Server Administration Tools (RSAT) installed. What if your computer is running Windows XP or Windows Vista? Are you out of luck? No. You can use implicit remoting.

Let's look at the entire process in a single example:

```
PS C:\> $session = new-pssession -comp server-r2      ← ① Establishes connection
PS C:\> invoke-command -command
➥{ import-module activedirectory }                  ← ② Loads remote module
➥-session $session
PS C:\> import-pssession -session $session
➥-module activedirectory                         ← ③ Imports remote commands
➥-prefix rem
ModuleType Name                                     ExportedCommands
----- -----
Script     tmp_2b9451dc-b973-495d... {Set-ADOrganizationalUnit, Get-ADD...
```

Reviews
temporary
local
module

4

Here's what's happening in that example:

- 1 We start by establishing a session with a remote computer that has the ActiveDirectory module installed ①. We need that computer to be running PowerShell v2 or later (which Windows Server 2008 R2 and later can do), and we must enable remoting.
- 2 We tell the remote computer to import its local ActiveDirectory module ②. That's just one example; we could have chosen to load any module, or even add a PSSnapin, if that's what we needed. Because the session is still open, the module stays loaded on the remote computer.
- 3 We then tell our computer to import the commands from that remote session ③. We want only the commands in the ActiveDirectory module, and when they're imported, we want a *rem* prefix to be added to each command's noun. That allows us to keep track of the remote commands more easily. It also means the commands won't conflict with any same-named commands already loaded into our shell.
- 4 PowerShell creates a temporary module on our computer that represents the remote commands ④. The commands aren't copied over; instead, PowerShell creates shortcuts for them, and those shortcuts point to the remote machine.

Now we can run the ActiveDirectory module commands, or even ask for help. Instead of running `New-ADUser`, we run `New-remADUser`, because we added that *rem* prefix to the commands' nouns. The commands remain available until we either close the shell or close that session with the remote computer. When we open a new shell, we have to repeat this process to regain access to the remote commands.

When we run these commands, they don't execute on our local machine. Instead, they're implicitly remoted to the remote computer. It executes them for us and sends the results to our computer.

We can envision a world where we don't ever install administrative tools on our computers again. What a hassle we'd avoid. Today, you need tools that can run on your computer's operating system and talk to whatever remote server you're trying to manage—and getting everything to match up can be impossible. In the future, you won't do that. You'll use implicit remoting. Servers will offer their management features as another service, via Windows PowerShell.

Now for the bad news: The results brought to your computer through implicit remoting are all deserialized, meaning that the objects' properties are copied into an XML file for transmission across the network. The objects you receive this way don't have any methods. In most cases, that's not a problem, but some modules and snap-ins produce objects that you're meant to use in a more programmatic way, and those don't lend themselves to implicit remoting. We hope you'll encounter few (if any) objects with this limitation, as a reliance on methods violates some PowerShell design practices. If you do run into such objects, you won't be able to use them through implicit remoting.

20.6 Using disconnected sessions

PowerShell v3 introduced two improvements to its remote-control capabilities.

First, sessions are much less fragile, meaning they can survive brief network hiccups and other transient interruptions. You get that benefit even if you aren't explicitly using a session object. Even if you've used `Enter-PSSession` and its `-ComputerName` parameter, you're technically still using a session under the hood, so you get the more-robust connectivity.

The other new feature introduced in v3 is one you have to explicitly use: disconnected sessions. Say you're sitting on COMPUTER1, logged in as Admin1 (who is a member of the Domain Admins group), and you create a new connection to COMPUTER2:

```
PS C:\> New-PSSession -ComputerName COMPUTER2
Id Name          ComputerName  State
-- --          -----
4 Session4      COMPUTER2    Opened
```

You can then disconnect that session. You still do this on COMPUTER1, where you're sitting, and it disengages the connection between the two computers, but it leaves the copy of PowerShell up and running on COMPUTER2. Note that you do this by specifying the session's ID number, which was displayed when you first created the session:

```
PS C:\> Disconnect-PSSession -Id 4
Id Name          ComputerName  State
-- --          -----
4 Session4      COMPUTER2    Disconnected
```

This is something you obviously need to think about—you're leaving a copy of PowerShell running on COMPUTER2. Assigning useful idle time-out periods and so forth becomes important. In earlier versions of PowerShell, a session that you disconnected went away, so you had no cleanup. Starting with v3, it's possible to litter your environment with running sessions, which means you have to exercise a bit more responsibility.

But here's the cool part: We'll log into another computer, COMPUTER3, as the same Domain Admin named Admin1, and retrieve a list of sessions running on COMPUTER2:

```
PS C:\> Get-PSSession -computerName COMPUTER2
Id Name          ComputerName  State
-- --          -----
4 Session4      COMPUTER2    Disconnected
```

Neat, right? You couldn't see this session if you'd logged in as a different user, even as another administrator; you can see only the sessions you created on COMPUTER2. But now, having seen it, you can reconnect it:

```
PS C:\> Get-PSSession -computerName COMPUTER2 | Connect-PSSession
Id Name          ComputerName  State
-- --          -----
4 Session4      COMPUTER2    Open
```

Let's spend some time talking about managing these sessions. In PowerShell's WSMAN: drive, you'll find settings that can help you keep disconnected sessions under control. You can also centrally configure most of these via Group Policy. The key settings to look for include the following:

- In WSMAN:\localhost\Shell:
 - `IdleTimeout` specifies the amount of time a session can be idle before it's shut down automatically. The default is about 2,000 hours (expressed in seconds), or about 84 days.
 - `MaxConcurrentUsers` specifies the number of users who can have a session open at once.
 - `MaxShellRunTime` determines the maximum amount of time a session can be open. The default is, for all practical purposes, infinite. Keep in mind that `IdleTimeout` can override this if the shell is sitting idle, as opposed to running commands.
 - `MaxShellsPerUser` sets a limit on the number of sessions a single user can have open at once. Multiply this by `MaxConcurrentUsers` to figure out the maximum possible number of sessions, for all users, on the computer.
- In WSMAN:\localhost\Service:
 - `MaxConnections` sets the upper limit on incoming connections to the entire remoting infrastructure. Even if you allow a larger number of shells per user or a maximum number of users, `MaxConnections` is the absolute limit on incoming connections.

As an administrator, you obviously have a higher level of responsibility than a plain old user. It's up to you to keep track of your sessions, particularly if you'll be disconnecting and reconnecting. Sensible time-out settings can help ensure that shell sessions don't sit around idling for long stretches of time.

20.7 Lab

NOTE For this lab, you need a Windows Server 2008 R2 or later running PowerShell v3 or later. If you have access to only a client computer (running Windows 7 or later), you won't be able to complete steps 6 through 9 of this lab.

To complete this lab, you should have two computers: one to remote from, and another to remote to. If you have only one computer, use its computer name to remote to it. You should get a similar experience that way.

TIP In chapter 1, we mentioned a multicomputer virtual environment at CloudShare (www.cloudshare.com). You'll find other, similar services that offer cloud-based virtual machines. By using CloudShare, we didn't have to set up the Windows OS, because the service had ready-made templates for us to use. You do have to pay a fee for the service, and it isn't available in all countries, but if you can use it, it's a great way to get a lab environment running if you're not able to run one locally.

- 1 Close all open sessions in your shell.
- 2 Establish a session to a remote computer. Save the session in a variable named \$session.
- 3 Use the \$session variable to establish a one-to-one remote shell session with the remote computer. Display a list of processes and then exit.
- 4 Use the \$session variable with Invoke-Command to get a list of services from the remote computer.
- 5 Use Get-PSSession and Invoke-Command to get a list of the 20 most recent Security event log entries from the remote computer.
- 6 Use Invoke-Command and your \$session variable to load the ServerManager module on the remote computer.
- 7 Import the ServerManager module's commands from the remote computer to your computer. Add the prefix *rem* to the imported commands' nouns.
- 8 Run the imported Get-WindowsFeature command.
- 9 Close the session that's in your \$session variable.

NOTE Thanks to a new feature in PowerShell v3, you could also accomplish steps 6 and 7 with a single step, by using the Import-Module command. Feel free to review the help for this command and see if you can figure out how to use it to import a module from a remote computer.

20.8 Further exploration

Take a quick inventory of your environment: What PowerShell-enabled products do you have? Exchange Server? SharePoint Server? VMware vSphere? System Center Virtual Machine Manager? These and other products all include PowerShell modules or snap-ins, many of which are accessible via PowerShell remoting.

20.9 Lab answers

```
1 get-pssession | Remove-PSSession
2 $session=new-pssession -computername localhost
3 enter-psession $session
Get-Process
Exit
4 invoke-command -ScriptBlock { get-service } -Session $session
5 Invoke-Command -ScriptBlock {get-eventlog -LogName System
➥-Newest 20} -Session (Get-PSSession)
6 Invoke-Command -ScriptBlock {Import-Module ServerManager}
➥-Session $session
7 Import-PSSession -Session $session -Prefix rem
➥-Module ServerManager
8 Get-RemWindowsFeature
9 Remove-PSSession -Session $session
```

You call this scripting?

So far, you could've accomplished everything in this book by using PowerShell's command-line interface. You haven't had to write a single script. That's a big deal for us, because we see a lot of administrators initially shying away from scripting, (rightly) perceiving it as a kind of programming, and (correctly) feeling that learning it can sometimes take more time than it's worth. Hopefully, you've seen how much you can accomplish in PowerShell without having to become a programmer.

But at this point, you may also be starting to feel that constantly retyping the same commands, over and over, is going to become pretty tedious. You're right, so in this chapter we're going to dive into PowerShell scripting—but we're still not going to be programming. Instead, we're going to focus on scripts as little more than a way of saving our fingers from unnecessary retyping.

21.1 Not programming, more like batch files

Most Windows administrators have, at one point or another, created a command-line batch file (which usually has a .BAT or .CMD filename extension). These are nothing more than simple text files that you can edit with Windows Notepad, containing a list of commands to be executed in a specific order. Technically, you call those commands a *script*, because like a Hollywood script, they tell the performer (your computer) exactly what to do and say, and in what order to do and say it. But batch files rarely look like programming, in part because the Cmd.exe shell has a limited language that doesn't permit incredibly complicated scripts.

PowerShell scripts—or *batch files*, if you prefer—work similarly. List the commands that you want run, and the shell will execute those commands in the order

specified. You can create a script by copying a command from the host window and pasting it into Notepad. Of course, Notepad is a pretty horrible text editor. We expect you'll be happier with the PowerShell ISE, or with a third-party editor such as Power-GUI, PrimalScript, or PowerShell Plus.

The ISE, in fact, makes “scripting” practically indistinguishable from using the shell interactively. When using the ISE’s Script Editor pane, you type the command or commands you want to run, and then click the Run button in the toolbar to execute those commands. Click Save and you’ve created a script without having to copy and paste anything at all.

21.2 Making commands repeatable

The idea behind PowerShell scripts is, first and foremost, to make it easier to run a given command over and over, without having to manually retype it every time. That being the case, we need to come up with a command that you’ll want to run over and over again, and use that as an example throughout this chapter. We want to make this decently complex, so we’ll start with something from WMI and add in some filtering, sorting, and other stuff.

At this point, we’re going to switch to using the PowerShell ISE instead of the normal console window, because the ISE will make it easier for us to migrate our command into a script. Frankly, the ISE makes it easier to type complex commands, because you get a full-screen editor instead of working on a single line within the console host.

Here’s our command:

```
Get-WmiObject -class Win32_LogicalDisk -computername localhost
➥-filter "drivetype=3" |
➥ Sort-Object -property DeviceID |
➥ Format-Table -property DeviceID,
➥ @{label='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
➥ @{label='Size(GB)';expression={$_.Size / 1GB -as [int]}},
➥ @{label='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
```

TIP Remember, you can use name instead of label, and either can be abbreviated to a single character, n or l. But it’s easy for a lowercase L to look like the number 1, so be careful!

Figure 21.1 shows how we enter this into the ISE. Notice that we select the two-pane layout by using the toolbar button on the far left of the layout choices. Also notice that we format our command so that each physical line ends in either a pipe character or a comma. By doing so, we’re forcing the shell to recognize these multiple lines as a single, one-line command. You could do the same thing in the console host, but this formatting is especially effective in the ISE because it makes the command a lot easier to read. Also notice that we use full cmdlet names and parameter names and that we specify every parameter name rather than using positional parameters. All of that will make our script easier to read and follow either for someone else, or in the future when we might have forgotten our original intent.

The screenshot shows the Windows PowerShell ISE window. At the top, the title bar reads "Administrator: Windows PowerShell ISE". Below the title bar is a toolbar with various icons. A red box highlights the green "Run" icon (a right-pointing arrow) in the toolbar. The main area is a code editor titled "Untitled1.ps1*". It contains the following PowerShell script:

```
1 Get-WmiObject -class Win32_LogicalDisk -computername localhost -filter "drivetype=3" |  
2 Sort-Object -property DeviceID |  
3 Format-Table -property DeviceID,  
4 @{label='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},  
5 @{label='Size(GB)';expression={$_.Size / 1GB -as [int]}},  
6 @{label='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}  
7
```

Below the code editor is a preview pane showing the output of the command. The output is a table with four columns: DeviceID, FreeSpace(MB), Size(GB), and %Free. The data is as follows:

DeviceID	FreeSpace(MB)	Size(GB)	%Free
C:	128176	188	67
D:	3259	30	11
E:	131	0	65

At the bottom of the ISE window, there is a status bar with the text "Completed" and some other information like "Ln 1 Col 1" and "145%".

Figure 21.1 Entering and running a command in the ISE

We run the command by clicking the green Run toolbar icon in the ISE (you could also press F5) to test it, and our output shows that it's working perfectly. Here's a neat trick in the ISE: You can highlight a portion of your command and press F8 to run just the highlighted portion. Because we've formatted the command so that there's one distinct command per physical line, that makes it easy for us to test our command bit by bit. We could highlight and run the first line independently. If we were satisfied with the output, we could highlight the first and second lines, and run them. If it worked as expected, we could run the whole command.

At this point, we can save the command—and we can start calling it a *script* now. We'll save it as `Get-DiskInventory.ps1`. We like giving scripts cmdlet-style verb-noun names. You can see how this script is going to start to look and work a lot like a cmdlet, so it makes sense to give it a cmdlet-style name.

TRY IT NOW We're assuming that you've already completed chapter 14 and enabled scripting by setting a more permissive execution policy. If you haven't done so, you should flip back to chapter 17 and complete its lab so that scripts will run in your copy of PowerShell.

21.3 Parameterizing commands

When you think about running a command over and over, you might realize that some portion of the command is going to have to change from time to time. For example, suppose you want to give `Get-DiskInventory.ps1` to some of your colleagues, who might be less experienced in using PowerShell. It's a complex, hard-to-type command, and they might appreciate having it bundled into an easier-to-run script. But,

as written, the script runs only against the local computer. You can certainly imagine that some of your colleagues might want to get a disk inventory from one or more remote computers instead.

One option is to have them open the script and change the `-computername` parameter's value. But it's entirely possible that they wouldn't be comfortable doing so, and there's a chance that they'll change something else and break the script entirely. It would be better to provide a formal way for them to pass in a different computer name (or a set of names). At this stage, you need to identify the things that might need to change when the command is run, and replace those things with variables.

We'll set the computer name variable to a static value for now, so that we can still test the script. Here's our revised script.

Listing 21.1 Get-DiskInventory.ps1, with a parameterized command

```
$computername = 'localhost'           ← ① Sets new variable
Get-WmiObject -class Win32_LogicalDisk ` ← ③ Uses variable
    -computername $computername ` ← ② Breaks line
    -filter "drivetype=3" |
Sort-Object -property DeviceID |
Format-Table -property DeviceID,
    @{{label='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}}},
    @{{label='Size(GB)';expression={$_.Size / 1GB -as [int]}}},
    @{{label='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}}
```

We do three things here, two of which are functional and one of which is purely cosmetic:

- We add a variable, `$computername`, and set it equal to `localhost` ①. We've noticed that most PowerShell commands that accept a computer name use the parameter name `-computername`, and we want to duplicate that convention, which is why we chose the variable name that we did.
- We replace the value for the `-computername` parameter with our variable ③. Right now, the script should run exactly the same as it did before (and we tested to make sure it does), because we put `localhost` into the `$computername` variable.
- We add a backtick after the `-computername` parameter and its value ②. This escapes, or takes away the special meaning of, the carriage return at the end of the line. That tells PowerShell that the next physical line is part of this same command. You don't need to do that when the line ends in a pipe character or a comma, but in order to fit the code within this book, we needed to break the line before the pipe character. This will work only if the backtick character is the last thing on the line!

Once again, we've been careful to run our script and verify that it's still working. We always do that after making any kind of change, to make sure we haven't introduced a random typo or other error.

21.4 Creating a parameterized script

Now that we've identified the elements of the script that might change from time to time, we need to provide a way for someone else to specify new values for those elements. We need to take that hardcoded \$computername variable and turn it into an input parameter.

PowerShell makes this easy.

Listing 21.2 Get-DiskInventory.ps1, with an input parameter

```
param (
    $computername = 'localhost'           ← ❶ Param block
)
Get-WmiObject -class Win32_LogicalDisk -computername $computername ` 
    -filter "drivetype=3" | 
Sort-Object -property DeviceID | 
Format-Table -property DeviceID,
    @{label='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
    @{label='Size(GB)';expression={$_.Size / 1GB -as [int]}},
    @{label='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
```

All we did was add a `Param()` block around our variable declaration ❶. This defines `$computername` as a parameter, and specifies that `localhost` is the default value to be used if the script is run without a computer name being specified. You don't have to provide a default value, but we like to do so when there's a reasonable value that we can think of.

All parameters declared in this fashion are both named and positional, meaning that we can now run the script from the command line in any of these ways:

```
PS C:\> .\Get-DiskInventory.ps1 server-r2
PS C:\> .\Get-DiskInventory.ps1 -computername server-r2
PS C:\> .\Get-DiskInventory.ps1 -comp server-r2
```

In the first instance, we use the parameter positionally, providing a value but not the parameter name. In the second and third instances, we specify the parameter name, but in the third instance we abbreviate that name in keeping with PowerShell's normal rules for parameter name abbreviation. Note that in all three cases, we have to specify a path (`.\`, which is the current folder) to the script, because the shell won't automatically search the current directory to find the script.

You can specify as many parameters as you need to by separating them with commas. For example, suppose that we want to also parameterize the filter criteria. Right now, it's retrieving only logical disks of type 3, which represents fixed disks. We could change that to a parameter, as in the following listing.

Listing 21.3 Get-DiskInventory.ps1, with an additional parameter

```
param (
    $computername = 'localhost',
    $drivetype = 3           ← Specifying additional
)                                parameter
```

```
Get-WmiObject -class Win32_LogicalDisk -computername $computername ` 
  -filter "drivetype=$drivetype" | 
  Sort-Object -property DeviceID | 
  Format-Table -property DeviceID, 
    @{label='FreeSpace (MB)';expression={$_.FreeSpace / 1MB -as [int]}}, 
    @{label='Size (GB)';expression={$_.Size / 1GB -as [int]}}, 
    @{label='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
```

Using parameter

Notice that we take advantage of PowerShell's ability to replace variables with their values inside double quotation marks (you learned about that trick in chapter 18).

We can run this script in any of the three original ways, although we could also omit either parameter if we wanted to use the default value for it. Here are some permutations:

```
PS C:\> .\Get-DiskInventory.ps1 server-r2 3
PS C:\> .\Get-DiskInventory.ps1 -comp server-r2 -drive 3
PS C:\> .\Get-DiskInventory.ps1 server-r2
PS C:\> .\Get-DiskInventory.ps1 -drive 3
```

In the first instance, we specify both parameters positionally, in the order in which they're declared within the `Param()` block. In the second case, we specify abbreviated parameter names for both. The third time, we omit `-drivetype` entirely, using the default value of 3. In the last instance, we leave off `-computername`, using the default value of localhost.

21.5 Documenting your script

Only a truly mean person would create a useful script and not tell anyone how to use it. Fortunately, PowerShell makes it easy to add help into your script, using comments. You're welcome to add typical programming-style comments to your scripts, but if you're using full cmdlet and parameter names, sometimes your script's operation will be obvious. By using a special comment syntax, however, you can provide help that mimics PowerShell's own help files.

This listing shows what we've added to our script.

Listing 21.4 Adding help to Get-DiskInventory.ps1

```
<#
.SYNOPSIS
Get-DiskInventory retrieves logical disk information from one or
more computers.
.DESCRIPTION
Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
instances from one or more computers. It displays each disk's
drive letter, free space, total size, and percentage of free
space.
.PARAMETER computername
The computer name, or names, to query. Default: Localhost.
.PARAMETER drivetype
The drive type to query. See Win32_LogicalDisk documentation
for values. 3 is a fixed disk, and is the default.
```

```
.EXAMPLE
Get-DiskInventory -computername SERVER-R2 -drivetype 3
#>
param (
    $computername = 'localhost',
    $drivetype = 3
)
Get-WmiObject -class Win32_LogicalDisk -computername $computername ` 
    -filter "drivetype=$drivetype" | 
    Sort-Object -property DeviceID | 
    Format-Table -property DeviceID,
    @{label='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
    @{label='Size(GB)';expression={$_.Size / 1GB -as [int]}},
    @{label='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
```

Normally, PowerShell ignores anything on a line that follows a # symbol, meaning that # designates a line as a comment. We use the <# #> block comment syntax instead, because we have several lines of comments and don't want to have to start each line with a separate # character.

Now we can drop to the normal console host and ask for help by running help .\Get-DiskInventory (again, you have to provide a path because this is a script and not a built-in cmdlet). Figure 21.2 shows the results, which proves that PowerShell is reading those comments and creating a standard help display. We can even run help .\Get-DiskInventory -full to get full help, including parameter information and our example. Figure 21.3 shows those results.

```
NAME
  C:\scripts\Get-DiskInventory.ps1

SYNOPSIS
  Get-DiskInventory retrieves logical disk information from one or
  more computers.

SYNTAX
  C:\scripts\Get-DiskInventory.ps1 [[-computername] <object>] [[-drivetype] <O

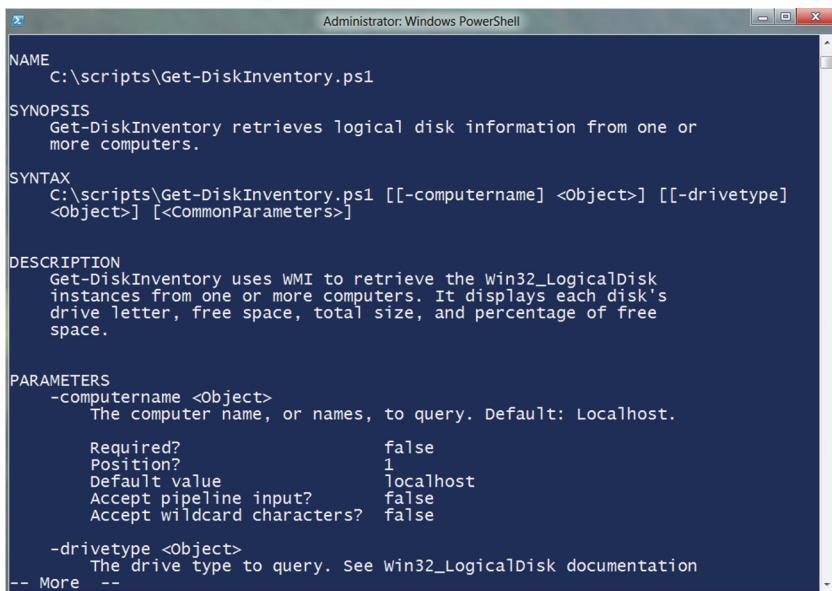

DESCRIPTION
  Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
  instances from one or more computers. It displays each disk's
  drive letter, free space, total size, and percentage of free
  space.

The screenshot shows a Windows PowerShell window titled "Administrator: Windows PowerShell". The command entered is "Get-DiskInventory.ps1". The output displays detailed help information:

```

NAME
  C:\scripts\Get-DiskInventory.ps1

SYNOPSIS
  Get-DiskInventory retrieves logical disk information from one or
  more computers.

SYNTAX
  C:\scripts\Get-DiskInventory.ps1 [[-computername] <Object>] [[-drivetype]
  <Object>] [<CommonParameters>]

DESCRIPTION
  Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
  instances from one or more computers. It displays each disk's
  drive letter, free space, total size, and percentage of free
  space.

PARAMETERS
  -computername <Object>
    The computer name, or names, to query. Default: Localhost.

    Required?          false
    Position?          1
    Default value      localhost
    Accept pipeline input?  false
    Accept wildcard characters?  false

  -drivetype <Object>
    The drive type to query. See Win32_LogicalDisk documentation
-- More --

```

Figure 21.3 Help options such as `-example`, `-detailed`, and `-full` are supported for comment-based help.

These special comments, called *comment-based help*, must appear at the beginning of your script file. There are several keywords in addition to `.DESCRIPTION`, `.SYNOPSIS`, and the others we've used. For a full list, run `help about_comment_based_help` in PowerShell.

21.6 One script, one pipeline

We normally tell folks that anything in a script will run exactly as if you manually typed it into the shell, or if you copied the script to the clipboard and pasted it into the shell. That's not entirely true, though.

Consider this simple script:

```
Get-Process
Get-Service
```

Just two commands. But what happens if you were to type those commands into the shell manually, hitting Enter after each?

TRY IT NOW Run these commands on your own to see the results; they create fairly long output that won't fit well within this book or even in a screenshot.

When you run the commands individually, you're creating a new pipeline for each command. At the end of each pipeline, PowerShell looks to see what needs to be formatted and creates the tables that you undoubtedly saw. The key here is that *each command runs in a separate pipeline*. Figure 21.4 illustrates this: two completely

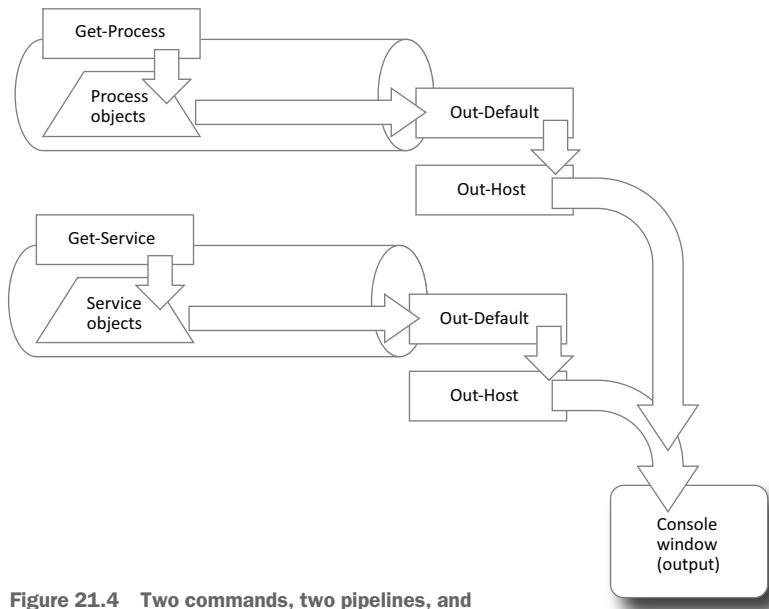

Figure 21.4 Two commands, two pipelines, and two sets of output in a single console window

separate commands, two individual pipelines, two formatting processes, and two different-looking sets of results.

You may think we're crazy for taking so much time to explain something that probably seems obvious, but it's important. Here's what happens when you run those two commands individually:

- 1 You run Get-Process.
- 2 The command places Process objects into the pipeline.
- 3 The pipeline ends in Out-Default, which picks up the objects.
- 4 Out-Default passes the objects to Out-Host, which calls on the formatting system to produce text output (you learned about this in chapter 10).
- 5 The text output appears on the screen.
- 6 You run Get-Service.
- 7 The command places Service objects into the pipeline.
- 8 The pipeline ends in Out-Default, which picks up the objects.
- 9 Out-Default passes the objects to Out-Host, which calls on the formatting system to produce text output.
- 10 The text output appears on the screen.

So you're now looking at a screen that contains the results from two commands. We want you to put those two commands into a script file. Name it Test.ps1 or something simple. Before you run the script, though, copy those two commands onto the clipboard. In the ISE, you can highlight both lines of text and press Ctrl-C to get them into the clipboard.

With those commands in the clipboard, go to the PowerShell console host and press Enter. That pastes the commands from the clipboard into the shell. They should execute exactly the same way, because the carriage returns also get pasted. Once again, you're running two distinct commands in two separate pipelines.

Now go back to the ISE and run the script. Different results, right? Why is that?

In PowerShell, every command executes within a single pipeline, and that includes scripts. Within a script, any command that produces pipeline output will be writing to a single pipeline: the one that the script itself is running in. Take a look at figure 21.5. We'll try to explain what happens:

- 1 The script runs `Get-Process`.
- 2 The command places `Process` objects into the pipeline.
- 3 The script runs `Get-Service`.
- 4 The command places `Service` objects into the pipeline.
- 5 The pipeline ends in `Out-Default`, which picks up both kinds of objects.
- 6 `Out-Default` passes the objects to `Out-Host`, which calls on the formatting system to produce text output.
- 7 Because the `Process` objects are first, the shell's formatting system selects a format appropriate to processes. That's why they look normal. But then the shell runs into the `Service` objects. It can't produce a whole new table at this point, so it winds up producing a list.
- 8 The text output appears on the screen.

This different output occurs because the script writes two kinds of objects to a single pipeline. This is the important difference between putting commands into a script and running them manually: Within a script, you have only one pipeline to work with. Normally, your scripts should strive to output only one kind of object, so that PowerShell can produce sensible text output.

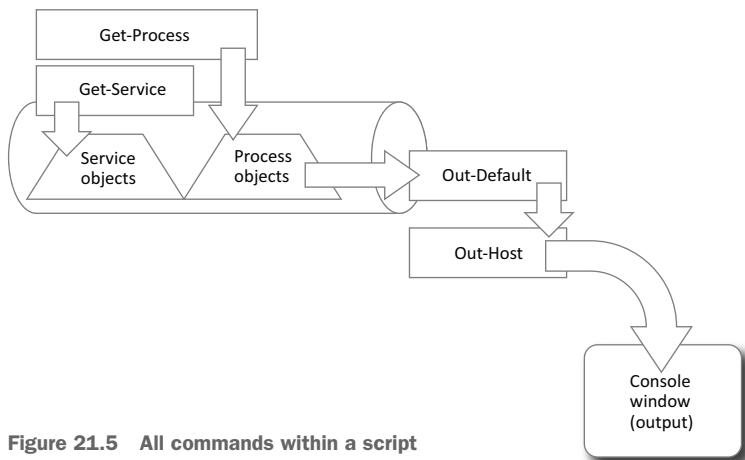

Figure 21.5 All commands within a script run within that script's single pipeline.

21.7 A quick look at scope

The last topic we need to visit is *scope*. Scopes are a form of container for certain types of PowerShell elements, primarily aliases, variables, and functions.

The shell itself is the top-level scope and is called the *global scope*. When you run a script, a new scope is created around that script, and it's called the *script scope*. The script scope is subsidiary to the global scope and is said to be a *child* of the global scope, which is the script scope's *parent*. Functions also get their own *private scope*.

Figure 21.6 illustrates these scope relationships, with the global scope containing its children, and those containing their own children, and so forth.

A scope lasts only as long as needed to execute whatever is in the scope. The global scope exists only while PowerShell is running, a script scope exists only while that script is running, and so forth. When whatever it is stops running, the scope vanishes, taking everything inside it with it. PowerShell has specific—and sometimes confusing—rules for scoped elements such as aliases, variables, and functions, but the main rule is this: If you try to access a scoped element, PowerShell sees whether it exists within the current scope. If it doesn't, PowerShell sees whether it exists in the current scope's parent. It continues going up the relationship tree until it gets to the global scope.

TRY IT NOW To get the proper results, it's important that you follow these steps carefully and precisely.

Let's see this in action. Follow these steps:

- 1 Close any PowerShell or PowerShell ISE windows you may have open, so that you can start from scratch.
- 2 Open a new PowerShell window and a new PowerShell ISE window.
- 3 In the ISE, create a script that contains one line: `Write $x`.
- 4 Save the script as `C:\Scope.ps1`.
- 5 In the regular PowerShell window, run the script with `C:\Scope`. You shouldn't see any output. When the script runs, a new scope is created for it. The `$x` variable doesn't exist in that scope, so PowerShell goes to the parent scope—the global scope—to see whether `$x` exists there. It doesn't exist there, either, so PowerShell decides that `$x` is empty, and writes that (meaning, nothing) as the output.
- 6 In the normal PowerShell window, run `$x = 4`. Then, run `C:\Scope` again. This time, you should see 4 as the output. The variable `$x` still isn't defined in the script scope, but PowerShell is able to find it in the global scope, and so the script uses that value.
- 7 In the ISE, add `$x = 10` to the top of the script (before the existing `Write` command), and save the script.

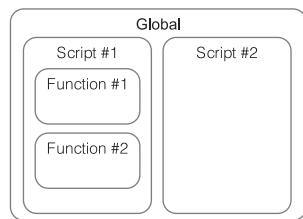

Figure 21.6 Global, script, and function (private) scopes

- 8 In the normal PowerShell window, run C:\Scope again. This time, you'll see 10 as output. That's because \$x is defined within the script scope, and the shell doesn't need to look in the global scope. Now run \$x in the shell. You'll see 4, proving that the value of \$x within the script scope doesn't affect the value of \$x within the global scope.

One important concept here is that when a scope defines a variable, alias, or function, that scope loses access to any variables, aliases, or functions having the same name in a parent scope. The locally defined element will always be the one PowerShell uses. For example, if you put New-Alias Dir Get-Service into a script, then within that script the alias Dir will run Get-Service instead of the usual Get-ChildItem. (In reality, the shell probably won't let you do that, because it protects the built-in aliases from being redefined.) By defining the alias within the script's scope, you prevent the shell from going to the parent scope and finding the normal, default Dir. Of course, the script's redefinition of Dir will last only for the execution of that script, and the default Dir defined in the global scope will remain unaffected.

It's easy to let this scope stuff confuse you. You can avoid confusion by never relying on anything that's in any scope other than the current one. So before you try to access a variable within a script, make sure you've already assigned it a value within that same scope. Parameters in a Param() block are one way to do that, and there are many other ways to put values and objects into a variable.

21.8 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

The following command is for you to add to a script. You should first identify any elements that should be parameterized, such as the computer name. Your final script should define the parameter, and you should create comment-based help within the script. Run your script to test it, and use the Help command to make sure your comment-based help works properly. Don't forget to read the help files referenced within this chapter for more information.

Here's the command:

```
Get-WmiObject Win32_LogicalDisk -comp $env:computername -filter
    ↪"drivetype=3" |
    ↪Where { ($_.FreeSpace / $_.Size) -lt .1 } |
    ↪Select -Property DeviceID,FreeSpace,Size
```

Here's a hint: At least two pieces of information need to be parameterized. This command is intended to list all drives that have less than a given amount of free disk space. Obviously, you won't always want to target localhost (we're using the PowerShell equivalent of %computername% in our example), and you might not want 10% (that is,.1) to be your free-space threshold. You could also choose to parameterize the drive type (which is 3, here), but for this lab leave that hardcoded with the value 3.

21.9 Lab answer

```
<#
.Synopsis
Get drives based on percentage free space
.Description
This command will get all local drives that have less than the specified
percentage of free space available.
.Parameter Computername
The name of the computer to check. The default is localhost.
.Parameter MinimumPercentFree
The minimum percent free diskspace. This is the threshhold. The default value
is 10. Enter a number between 1 and 100.
.Example
PS C:\> Get-Disk -minimum 20

Find all disks on the local computer with less than 20% free space.
.Example
PS C:\> Get-Disk -comp SERVER02 -minimum 25

Find all local disks on SERVER02 with less than 25% free space.
#>

Param (
$Computername='localhost',
$MinimumPercentFree=10
)

#Convert minimum percent free
$minpercent = $MinimumPercentFree/100

Get-WmiObject -class Win32_LogicalDisk -computername $computername -filter
"drivetype=3" |
Where { $_.FreeSpace / $_.Size -lt $minpercent } |
Select -Property DeviceID,FreeSpace,Size
```

Improving your parameterized script

In the previous chapter, we left you with a pretty cool script that had been parameterized. The idea of a parameterized script is that someone else can run the script without having to worry about or mess with its contents. Script users provide input through a designated interface—parameters—and that's all they can change. In this chapter, we're going to take things a bit further.

22.1 Starting point

Just to make sure we're on the same page, let's agree to use listing 22.1 as a starting point. This script features comment-based help, two input parameters, and a command that uses those input parameters. We've made one minor change since the previous chapter: We changed the output to be selected objects, rather than a formatted table.

Listing 22.1 Starting point: Get-DiskInventory.ps1

```
<#
.SYNOPSIS
Get-DiskInventory retrieves logical disk information from one or
more computers.
.DESCRIPTION
Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
instances from one or more computers. It displays each disk's
drive letter, free space, total size, and percentage of free
space.
```

```
.PARAMETER computername
The computer name, or names, to query. Default: Localhost.
.PARAMETER drivetype
The drive type to query. See Win32_LogicalDisk documentation
for values. 3 is a fixed disk, and is the default.
.EXAMPLE
Get-DiskInventory -computername SERVER-R2 -drivetype 3
#>
param (
    $computername = 'localhost',
    $drivetype = 3
)
Get-WmiObject -class Win32_LogicalDisk -computername $computername ` 
    -filter "drivetype=$drivetype" |
    Sort-Object -property DeviceID |
    Select-Object -property DeviceID,
    @{name='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
    @{name='Size(GB)';expression={$_.Size / 1GB -as [int]}},
    @{name='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
```

Why did we switch to `Select-Object` instead of `Format-Table`? We generally feel it's a bad idea to write a script that produces preformatted output. After all, if someone needed this data in a CSV file, and the script was outputting formatted tables, that person would be out of luck. With this revision, we can run our script this way to get a formatted table:

```
PS C:\> .\Get-DiskInventory | Format-Table
```

Or we could run it this way to get that CSV file:

```
PS C:\> .\Get-DiskInventory | Export-Csv disks.csv
```

The point is that outputting objects (which `Select-Object` does), as opposed to formatted displays, makes our script more flexible in the long run.

22.2 Getting PowerShell to do the hard work

We're going to turn on some PowerShell magic by adding just one line to our script. This technically turns our script into an *advanced script*, which enables a whole slew of useful PowerShell capabilities. The following listing shows the revision.

Listing 22.2 Making Get-DiskInventory.ps1 an advanced script

```
<#
.SYNOPSIS
Get-DiskInventory retrieves logical disk information from one or
more computers.
.DESCRIPTION
Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
instances from one or more computers. It displays each disk's
drive letter, free space, total size, and percentage of free
space.
.PARAMETER computername
```

```
The computer name, or names, to query. Default: Localhost.
.PARAMETER drivetype
The drive type to query. See Win32_LogicalDisk documentation
for values. 3 is a fixed disk, and is the default.
.EXAMPLE
Get-DiskInventory -computername SERVER-R2 -drivetype 3
#>
[CmdletBinding()]
param (
    $computername = 'localhost',
    $drivetype = 3
)
Get-WmiObject -class Win32_LogicalDisk -computername $computername ^
    -filter "drivetype=$drivetype" |
    Sort-Object -property DeviceID |
    Select-Object -property DeviceID,
        @{name='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
        @{name='Size(GB)';expression={$_.Size / 1GB -as [int]}},
        @{name='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
```

It's important that the `[CmdletBinding()]` directive be the first line in the script after the comment-based help. PowerShell knows to look for it only there. With this one change, the script will continue to run normally, but we've enabled several neat features that we'll explore next.

22.3 Making parameters mandatory

We're a little unhappy with our script in its existing form because it provides a default value for the `-ComputerName` parameter—and we're not sure one is really needed. We'd rather prompt for that value than rely on a hardcoded default. Fortunately, PowerShell makes it easy—again, adding just one line will do the trick, as shown in the next listing.

Listing 22.3 Giving Get-DiskInventory.ps1 a mandatory parameter

```
<#
.SYNOPSIS
Get-DiskInventory retrieves logical disk information from one or
more computers.
.DESCRIPTION
Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
instances from one or more computers. It displays each disk's
drive letter, free space, total size, and percentage of free
space.
.PARAMETER computername
The computer name, or names, to query. Default: Localhost.
.PARAMETER drivetype
The drive type to query. See Win32_LogicalDisk documentation
for values. 3 is a fixed disk, and is the default.
.EXAMPLE
Get-DiskInventory -computername SERVER-R2 -drivetype 3
#>
[CmdletBinding()]
param (
```

```
[Parameter(Mandatory=$True)]
[string]$computername,
[int]$drivetype = 3
)
Get-WmiObject -class Win32_LogicalDisk -computername $computername ` 
-filter "drivetype=$drivetype" |
Sort-Object -property DeviceID |
Select-Object -property DeviceID,
@{name='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
@{name='Size(GB)';expression={$_.Size / 1GB -as [int]}},
@{name='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
```

Above and beyond

When someone runs your script but doesn't provide a mandatory parameter, PowerShell will prompt them for it. There are two ways to make PowerShell's prompt more meaningful to that user.

First, use a good parameter name. Prompting someone to fill in `comp` isn't as helpful as prompting them to provide a `computerName`, so try to use parameter names that are descriptive and consistent with what other PowerShell commands use.

You can also add a help message:

```
[Parameter(Mandatory=$True, HelpMessage="Enter a computer name to query")]
```

Some PowerShell hosts will display that help message as part of the prompt, making it even clearer to the user, but not every host application will use this attribute, so don't be dismayed if you don't see it all the time as you're testing. We like including it anyway, when we're writing something intended to be used by other people. It never hurts. But for brevity, we'll omit `HelpMessage` from our running example in this chapter.

Just that one *decorator*, `[Parameter(Mandatory=$True)]`, will make PowerShell prompt for a computer name if whoever runs this script forgets to provide one. To help PowerShell even further, we've given both of our parameters a data type: `[string]` for `-computername`, and `[int]` (which means integer) for `-drivetype`.

Adding these kinds of attributes to parameters can become confusing, so let's examine the `Param()` block syntax more closely—look at figure 22.1.

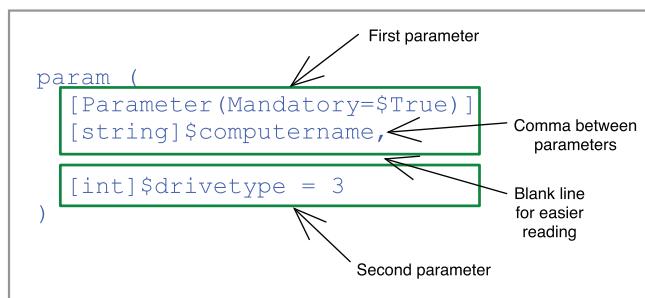

Figure 22.1 Breaking down the `Param()` block syntax

Here are the important things to notice:

- All of the parameters are enclosed within the `Param()` block's parentheses.
- A single parameter can consist of multiple decorators, which can either be strung out on one line, or placed on separate lines as we've done in figure 22.1. We think multiple lines are more readable—but the important bit is that they all go together. Here, the `Mandatory` attribute modifies only `-computerName`; it has no effect at all on `-drivetype`.
- Each parameter name except the last one is followed by a comma.
- For better readability, we also like to put a blank line between parameters. We think it helps to visually separate them better, making the `Param()` block less confusing.
- We define each parameter as if it were a variable—`$computername` and `$-drivetype`—but someone who runs this script will treat them as normal PowerShell command-line parameters, such as `-computername` and `-drivetype`.

TRY IT NOW Try saving the script in listing 22.3 and running it in the shell. Don't specify a `-computername` parameter and see how PowerShell prompts you for that information.

22.4 Adding parameter aliases

Is `computername` the first thing that comes to mind when you think about computer names? Possibly not. We used `-computerName` as our parameter name because it's consistent with the way other PowerShell commands are written. Look at `Get-Service`, `Get-WmiObject`, `Get-Process`, and others, and you'll see a `-computerName` parameter on them all. So we went with that.

But if something like `-hostname` comes more easily to your mind, you can add that as an alternative name, or alias, for the parameter. It's just another decorator, as shown in the following listing.

Listing 22.4 Adding a parameter alias to Get-DiskInventory.ps1

```
<#
.SYNOPSIS
Get-DiskInventory retrieves logical disk information from one or
more computers.
.DESCRIPTION
Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
instances from one or more computers. It displays each disk's
drive letter, free space, total size, and percentage of free
space.
.PARAMETER computername
The computer name, or names, to query. Default: Localhost.
.PARAMETER drivetype
The drive type to query. See Win32_LogicalDisk documentation
for values. 3 is a fixed disk, and is the default.
.EXAMPLE
Get-DiskInventory -computername SERVER-R2 -drivetype 3
```

```
#>
[CmdletBinding()]
param (
    [Parameter(Mandatory=$True)]
    [Alias('hostname')]
    [string]$computername,
    [int]$drivetype = 3
)
Get-WmiObject -class Win32_LogicalDisk -computername $computername ` 
    -filter "drivetype=$drivetype" |
    Sort-Object -property DeviceID |
    Select-Object -property DeviceID,
    @{name='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
    @{name='Size(GB)';expression={$_.Size / 1GB -as [int]}},
    @{name='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
```

With this minor change, we can now run this:

```
PS C:\> .\Get-DiskInventory -host SERVER2
```

NOTE Remember, you have to type only enough of a parameter name for PowerShell to understand which parameter you meant. In this case, `-host` was enough for PowerShell to identify `-hostname`. We could also have typed the full thing.

Again, this new addition is a part of the `-computername` parameter; it has no effect on `-drivetype`. The `-computername` parameter's definition now occupies three lines of text, although we could also have strung everything together on one line:

```
[Parameter(Mandatory=$True)] [Alias('hostname')] [string]$computername,
```

We just think that's a lot harder to read.

22.5 Validating parameter input

Let's play with the `-drivetype` parameter a little bit. According to the MSDN documentation for the `Win32_LogicalDisk` WMI class (do a search for the class name, and one of the top results will be the documentation), drive type 3 is a local hard disk. Type 2 is a removable disk, which should also have a size and free space measurement. Drive types 1, 4, 5, and 6 are less interesting (does anyone use RAM drives, type 6, anymore?), and in some cases they might not have an amount of free space (type 5, for optical disks). So we'd like to prevent anyone from using those types when they run our script.

This listing shows the minor change we need to make.

Listing 22.5 Adding parameter validation to Get-DiskInventory.ps1

```
<#
.SYNOPSIS
Get-DiskInventory retrieves logical disk information from one or
more computers.
.DESCRIPTION
```

```

Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
instances from one or more computers. It displays each disk's
drive letter, free space, total size, and percentage of free
space.
.PARAMETER computername
The computer name, or names, to query. Default: Localhost.
.PARAMETER drivetype
The drive type to query. See Win32_LogicalDisk documentation
for values. 3 is a fixed disk, and is the default.
.EXAMPLE
Get-DiskInventory -computername SERVER-R2 -drivetype 3
#>
[CmdletBinding()]
param (
    [Parameter(Mandatory=$True)]
    [Alias('hostname')]
    [string]$computername,
    [ValidateSet(2,3)]
    [int]$drivetype = 3
)
Get-WmiObject -class Win32_LogicalDisk -computername $computername ^
    -filter "drivetype=$drivetype" |
    Sort-Object -property DeviceID |
    Select-Object -property DeviceID,
        @{$name='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
        @{$name='Size(GB)';expression={$_.Size / 1GB -as [int]}},
        @{$name='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}

```

This new decorator tells PowerShell that only two values, 2 and 3, are accepted by our `-drivetype` parameter, and that 3 is the default.

There are a bunch of other validation techniques you can add to a parameter, and when it makes sense to do so, you can add more than one to the same parameter. Run `help about_functions_advanced_parameters` for a full list. We'll stick with `ValidateSet()` for now. Jeffery also wrote a great set of blog articles on some of the other Validate attributes that might be helpful; you can look it up at <http://jdhitsolutions.com> (search for *validate*).

TRY IT NOW Save this script and run it again. Try specifying `-drivetype 5` and see what PowerShell does.

22.6 Adding the warm and fuzzies with verbose output

In chapter 19, we mentioned how we prefer to use `Write-Verbose` over `Write-Host` for producing the step-by-step progress information that some folks like to see their scripts produce. Now's the time for a real example.

We've added a few verbose output messages in this listing.

Listing 22.6 Adding verbose output to Get-DiskInventory.ps1

```

<#
.SYNOPSIS
Get-DiskInventory retrieves logical disk information from one or

```

```

more computers.

.DESCRIPTION
Get-DiskInventory uses WMI to retrieve the Win32_LogicalDisk
instances from one or more computers. It displays each disk's
drive letter, free space, total size, and percentage of free
space.

.PARAMETER computername
The computer name, or names, to query. Default: Localhost.

.PARAMETER drivetype
The drive type to query. See Win32_LogicalDisk documentation
for values. 3 is a fixed disk, and is the default.

.EXAMPLE
Get-DiskInventory -computername SERVER-R2 -drivetype 3
#>
[CmdletBinding()]
param (
    [Parameter(Mandatory=$True)]
    [Alias('hostname')]
    [string]$computername,
    [ValidateSet(2,3)]
    [int]$drivetype = 3
)
Write-Verbose "Connecting to $computername"
Write-Verbose "Looking for drive type $drivetype"
Get-WmiObject -class Win32_LogicalDisk -computername $computername ` 
    -filter "drivetype=$drivetype" |
    Sort-Object -property DeviceID |
    Select-Object -property DeviceID,
        @{name='FreeSpace(MB)';expression={$_.FreeSpace / 1MB -as [int]}},
        @{name='Size(GB)';expression={$_.Size / 1GB -as [int]}},
        @{name='%Free';expression={$_.FreeSpace / $_.Size * 100 -as [int]}}
Write-Verbose "Finished running command"

```

Now try running this script in two ways. This first attempt shouldn't display any of the verbose output:

```
PS C:\> .\Get-DiskInventory -computername localhost
```

Now for a second attempt, where we want the verbose output displayed:

```
PS C:\> .\Get-DiskInventory -computername localhost -verbose
```

TRY IT NOW This is a lot cooler when you see it for yourself. Run the script as we've shown here, and see the differences for yourself.

How cool is that? When you want verbose output, you can get it—and you don't have to code the `-Verbose` parameter at all! It comes for free when you add `[-Cmdlet-Binding()]`. And a really neat part is that it will also activate verbose output for every command that your script contains! So any commands you use that are designed to produce verbose output will do so “automagically.” This technique makes it easy to turn the verbose output on and off, making it a lot more flexible than `Write-Host`. And you don't have to mess around with the `$VerbosePreference` variable to make the output show up onscreen.

Also, notice in the verbose output how we made use of PowerShell's double quotation mark trick: By including a variable (`$computername`) within double quotes, the output is able to include the contents of the variable, so we can see what PowerShell is up to.

22.7 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

This lab requires you to recall some of what you learned in chapter 21, because you'll be taking the following command, parameterizing it, and turning it into a script—just as you did for the lab in chapter 21. But this time we also want you to make the `-computerName` parameter mandatory and give it a hostname alias. Have your script display verbose output before and after it runs this command, too. Remember, you have to parameterize the computer name—but that's the only thing you have to parameterize in this case.

Be sure to run the command as is before you start modifying it, to make sure it works on your system:

```
get-wmiobject win32_networkadapter -computername localhost |
  where { $_.PhysicalAdapter } |
    select MACAddress,AdapterType,DeviceID,Name,Speed
```

To reiterate, here's your complete task list:

- Make sure the command runs as is before modifying it.
- Parameterize the computer name.
- Make the computer name parameter mandatory.
- Give the computer name parameter an alias, `hostname`.
- Add comment-based help with at least one example of how to use the script.
- Add verbose output before and after the modified command.
- Save the script as `Get-PhysicalAdapters.ps1`.

22.8 Lab answer

```
#Get-PhysicalAdapters.ps1

<#
.Synopsis
Get physical network adapters
.Description
Display all physical adapters from the Win32_NetworkAdapter class.
.Parameter Computername
The name of the computer to check.
.Example
PS C:\> c:\scripts\Get-PhysicalAdapters -computer SERVER01
#>
[cmdletbinding()]
Param (
[Parameter(Mandatory=$True,HelpMessage="Enter a computername to query")]
```

```
[alias('hostname')]
[string]$Computername
)

Write-Verbose "Getting physical network adapters from $computername"
Get-Wmiobject -class win32_networkadapter -computername $computername |
    where { $_.PhysicalAdapter } |
        select MACAddress,AdapterType,DeviceID,Name,Speed
Write-Verbose "Script finished."
```

Advanced remoting configuration

In chapter 13, we did our best to introduce you to PowerShell’s remoting technology. We deliberately left a few stones unturned in order to focus on the core technologies and techniques behind remoting, but in this chapter we want to return and cover some of the more advanced and unusual features and scenarios. We admit up front that not everything in this chapter will be usable by everyone—but we do think everyone should know about these options, in case a need for them arises in your future.

Also, we quickly remind you that this book is focused on PowerShell v3 and later, which all feature essentially the same remoting features. Revisit chapter 1 if you need help in figuring out which version you’re running; much of what we cover in this book won’t work in older versions.

23.1 Using other endpoints

As you learned in chapter 13, a single computer can contain multiple *endpoints*, which PowerShell also refers to as *session configurations*. For example, enabling remoting on a 64-bit machine enables an endpoint for 32-bit PowerShell as well as 64-bit PowerShell, with the 64-bit one being the default.

You can see a list of available session configurations on any machine you have administrator access to:

```
PS C:\> Get-PSSessionConfiguration

Name      : microsoft.powershell
PSVersion : 3.0
StartupScript :
RunAsUser :
Permission : NT AUTHORITY\NETWORK AccessDenied, BUILTIN\Administrators
             AccessAllowed
Name      : microsoft.powershell.workflow
PSVersion : 3.0
StartupScript :
RunAsUser :
Permission : NT AUTHORITY\NETWORK AccessDenied, BUILTIN\Administrators
             AccessAllowed
Name      : microsoft.powershell32
PSVersion : 3.0
StartupScript :
RunAsUser :
Permission : NT AUTHORITY\NETWORK AccessDenied, BUILTIN\Administrators
             AccessAllowed
```

Each endpoint has a name; the one named Microsoft.PowerShell is the one that remoting commands such as `New-PSSession`, `Enter-PSSession`, `Invoke-Command`, and so forth use by default. On a 64-bit system, that endpoint is the 64-bit shell; on a 32-bit system, Microsoft.PowerShell is a 32-bit shell.

You'll notice that our 64-bit system has an alternative Microsoft.PowerShell32 endpoint running a 32-bit shell for backward compatibility. To connect to an alternative endpoint, specify its name to the `-ConfigurationName` parameter of a remoting command:

```
PS C:\> Enter-PSSession -ComputerName DONJONES1D96 -ConfigurationName
➥ 'Microsoft.PowerShell32'

[DONJONES1D96] : PS C:\Users\donjones\Documents>
```

When might you use an alternative endpoint? Well, if you need to run a command that relies on a 32-bit PSSnapin, that might be one reason to explicitly connect to the 32-bit endpoint on a 64-bit machine. You might also have custom endpoints set up, and might need to connect to one in order to perform a specific task.

23.2 Creating custom endpoints

Creating a custom endpoint is a two-step process:

- 1 You use `New-PSSessionConfigurationFile` to create a new session configuration file, which should have a .PSSC filename extension. This file defines many characteristics of the endpoint, predominantly the commands and capabilities it will include.
- 2 You use `Register-PSSessionConfiguration` to load the .PSSC file and create the new endpoint within the WinRM service. During registration, you can set numerous operational parameters, such as defining who may connect to the endpoint. You can change those settings later by using `Set-PSSession-Configuration`, if necessary.

In this section, we'll walk through an example that uses custom endpoints for delegated administration, which is possibly one of their coolest features. We'll create an endpoint that members of our domain's HelpDesk group can connect to. Within that endpoint, we'll enable the commands that relate to network adapter management—and only those commands. We don't plan to give our help desk permission to run those commands, just to make the commands visible to them. We'll also configure the endpoint to run commands under an alternative credential that we provide, so the commands will work without our help desk team having the necessary permissions themselves.

23.2.1 Creating the session configuration

Here's the command we run (we format this nicely for the book, but it's typed as one long line):

```
PS C:\> New-PSSessionConfigurationFile
  ↪ -Path C:\HelpDeskEndpoint.pssc
  ↪ -ModulesToImport NetAdapter
  ↪ -SessionType RestrictedRemoteServer
  ↪ -CompanyName "Our Company"
  ↪ -Author "Don Jones"
  ↪ -Description "Net adapter commands for use by help desk"
  ↪ -PowerShellVersion '3.0'
```

A couple of key parameters are here, which are highlighted in bold. Here, we explain why we chose these values, but we leave it up to you to read the help on this command to discover its other options:

- The **-Path** is required, and the filename you provide should end in .PSSC.
- **-ModulesToImport** lists the modules (in this case, just one named `NetAdapter`) that we want available within this endpoint.
- **-SessionType RestrictedRemoteServer** removes all core PowerShell commands, except for a short list of necessary ones. Those include `Select-Object`, `Measure-Object`, `Get-Command`, `Get-Help`, `Exit-PSSession`, and so on.
- **-PowerShellVersion** defaults to 3.0, but we included it for completeness.

Several parameters also are available that start with **-Visible**, such as **-Visible-Cmdlets**. Normally, when you import a module using **-ModulesToImport**, every command in the module is made visible to people using the final endpoint, but you can use the **-Visible** parameters to change that behavior. By listing just the cmdlets, aliases, functions, and providers you want people to see, you're hiding the rest. That's a good way to limit what someone can do with your endpoint. Do be careful when using these visibility parameters, as they can be a bit confusing. For example, if you import a module consisting of both cmdlets and functions, then using **-Visible-Cmdlets** restricts only which of the cmdlets are visible—but it has no effect on the visible functions, meaning they all remain visible by default.

Note that there's no way to limit the parameters commands can use: PowerShell supports parameter-level restrictions, but to obtain that ability, you have to do some heavier-duty coding in Visual Studio, which is beyond what we cover in this book. You can use other, advanced tricks, such as creating proxy functions that hide specific parameters, but those are also beyond the scope of this book for beginners.

23.2.2 Registering the session

Having created the session configuration file, here's the command we run to get it up and running. Again, we format this nicely for the book, but we type it all on one long command line:

```
PS C:\> Register-PSSessionConfiguration  
➥ -Path .\HelpDeskEndpoint.pssc  
➥ -RunAsCredential COMPANY\HelpDeskProxyAdmin  
➥ -ShowSecurityDescriptorUI  
➥ -Name HelpDesk
```

This creates a new endpoint named HelpDesk (as opposed to Microsoft.PowerShell or something else). As shown in figure 23.1, we are prompted for the password for the COMPANY\HelpDeskProxyAdmin account; this is the account that will be used to run all commands within the endpoint. We make sure that account has the permissions needed to run the network adapter commands.

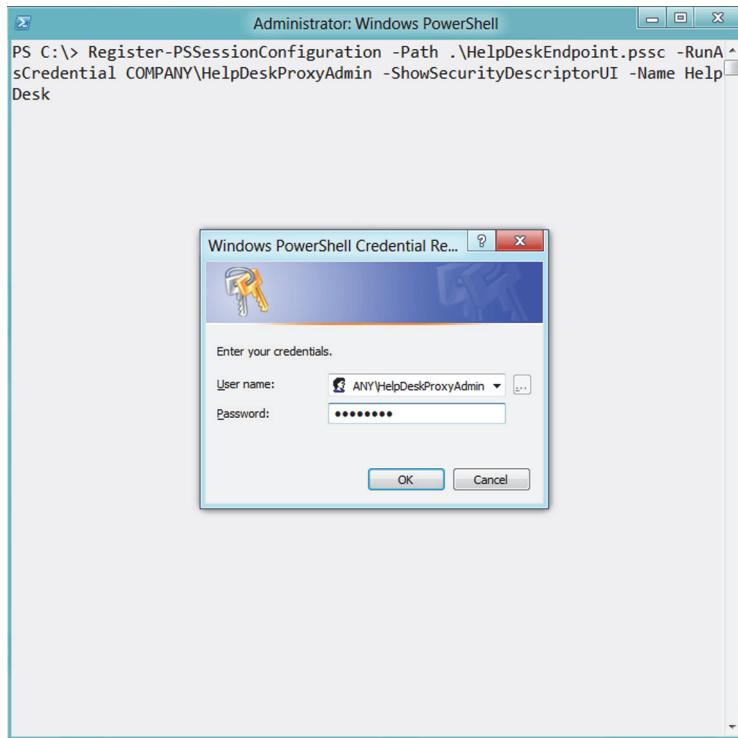

Figure 23.1 Password prompt for our “run as” credential

We have to answer several “are you sure” prompts, which we strongly suggest that you read carefully. This command will stop and restart the WinRM service, for example, which could interrupt other administrators attempting to manage the local machine, so some caution is in order.

As shown in figure 23.2, we are also given a graphical dialog box to specify which users may connect to the endpoint. The dialog box is displayed because we used the `-ShowSecurityDescriptorUI` parameter, rather than specifying the endpoint’s permissions in the complex Security Descriptor Definition Language (SDDL), which we’re frankly not all that familiar with. This is a case where the GUI is a good thing—we add our HelpDesk user group to it, and ensure those users have Execute and Read permissions. Execute is the minimum permission needed, given what we plan to have them doing with the endpoint; Read is the only other thing they should need.

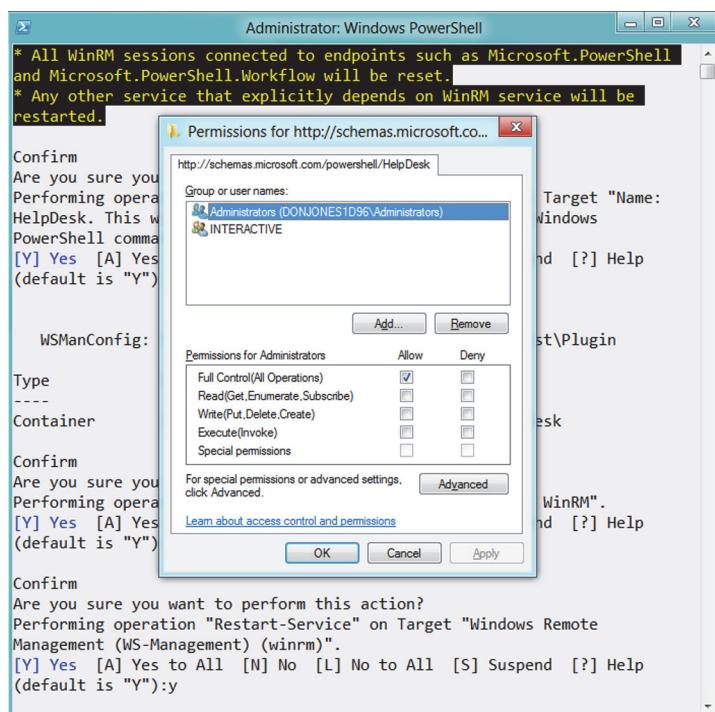

Figure 23.2 Setting the endpoint’s permissions

With that, we’re finished. As you can see from the following (truncated) output, users of our new endpoint have a limited set of commands to work with:

```
PS C:\> Enter-PSSession -ComputerName DONJONES1D96 -ConfigurationName
      HelpDesk
```

```
[DONJONES1D96] : PS>Get-Command
```

Capability	Name	ModuleName
CIM	Disable-NetAdapter	NetA...
CIM	Disable-NetAdapterBinding	NetA...
CIM	Disable-NetAdapterChecksumOffload	NetA...
CIM	Disable-NetAdapterEncapsulatedPacketTaskOffload	NetA...
CIM	Disable-NetAdapterIPsecOffload	NetA...
CIM	Disable-NetAdapterLso	NetA...
CIM	Disable-NetAdapterPowerManagement	NetA...
CIM	Disable-NetAdapterQos	NetA...
CIM	Disable-NetAdapterRdma	NetA...
CIM	Disable-NetAdapterRsc	NetA...
CIM	Disable-NetAdapterRss	NetA...
CIM	Disable-NetAdapterSriov	NetA...
CIM	Disable-NetAdapterVmq	NetA...
CIM	Enable-NetAdapter	NetA...
CIM	Enable-NetAdapterBinding	NetA...
CIM	Enable-NetAdapterChecksumOffload	NetA...
CIM	Enable-NetAdapterEncapsulatedPacketTaskOffload	NetA...
CIM	Enable-NetAdapterIPsecOffload	NetA...
CIM	Enable-NetAdapterLso	NetA...
CIM	Enable-NetAdapterPowerManagement	NetA...
CIM	Enable-NetAdapterQos	NetA...

This is a great way to create a specific set of capabilities for a group of users. They don't even necessarily need to connect to PowerShell from a console session as we did for this test; they might be using a GUI tool that utilizes PowerShell remoting under the hood. Provided that tool needs only these commands, this technique is a great way to give someone this delegated capability and nothing else.

23.3 Enabling multihop remoting

Enabling multihop remoting is a topic we briefly brought up in chapter 13, but it deserves a bit more depth. Figure 23.3 depicts the *second hop* or *multihop* problem: You start on Computer A, and you create a PSSession connection to Computer B. That's the first hop, and it'll probably work fine. But then you try to ask Computer B to create a second hop, or connection, to Computer C, and the operation fails.

The problem is related to the way PowerShell delegates your credentials from Computer A to Computer B. *Delegation* is the process of enabling Computer B to execute tasks as if it were you, thus ensuring that you

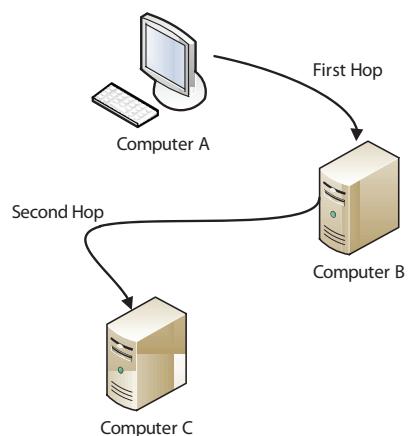

Figure 23.3 Multihop remoting in Windows PowerShell

can do anything you'd normally have permission to do, but nothing more. By default, delegation can traverse only one such hop; Computer B doesn't have permission to delegate your credential on to a third computer, Computer C.

On Windows Vista and later, you can enable this multihop delegation. Two steps are needed:

- 1 On your computer (Computer A in the example), run `Enable-WSManCredSSP -Role Client -DelegateComputer x`. You replace `x` with the name of the computer that your credentials may be delegated to. You could specify an individual computer name, but you might also use wildcards. We don't recommend using `*`, as that presents real security concerns, but you might authorize an entire domain: `*.company.com`, for example.
- 2 On the server that you're connecting to first (Computer B in the example), run `Enable-WSManCredSSP -Role Server`.

The changes made by the command are applied to the computers' local security policy; you could also manually make these changes via a Group Policy object, which might make more sense in a large domain environment. Managing this via Group Policy is beyond the scope of this chapter, but you can find more information in the help for `Enable-WSManCredSSP`. Don also authored a *Secrets of PowerShell Remoting* guide (available at PowerShell.org) that covers the policy-related elements in more detail.

23.4 Digging deeper into remoting authentication

We find that folks tend to think of authentication as a one-way process: You want to access a remote machine, and you have to provide it with your credentials before it will let you in. But PowerShell remoting employs *mutual authentication*, which means the remote machine must also prove its identity to you. If you run `Enter-PSSession -computerName DC01`, the computer named DC01 has to prove it's DC01 before the connection will complete.

Why? Normally, your computer resolves a computer name (for example, DC01) to an IP address by using the Domain Name System (DNS). DNS isn't invulnerable to spoofing, so it's not unthinkable that an attacker could get in and modify the entry for DC01 to point to a different IP address—an IP address that the attacker controls. You could unknowingly connect to DC01, wind up on an imposter computer, and then start delegating your credential to it—bad news! Mutual authentication prevents that from happening: If the computer you connect to can't prove it's the one you intended to connect to, then remoting will fail. That's a good thing; you don't want to turn that protection off without careful planning and consideration.

23.4.1 Defaults for mutual authentication

Microsoft expects most PowerShell usage to occur in an Active Directory domain environment. Provided you connect to computers by using their real computer names, as listed in Active Directory, the domain will handle the mutual authentication for you.

This even happens when you access computers in other, trusting domains. The trick is that you need to provide PowerShell with a computer name that meets both of these requirements:

- The name must resolve to an IP address.
- The name must match the computer's name in the directory.

Providing a computer name from the same domain that you're in, or a fully qualified name (computer and domain name, such as DC01.COMPANY.LOC) for a trusting domain, usually accomplishes both of these tasks. But if you need to provide an IP address, or if you need to provide a different name for DNS to work (such as a CNAME alias), then the default mutual authentication won't work. That leaves you with two choices: SSL or TrustedHosts.

23.4.2 Mutual authentication via SSL

To accomplish mutual authentication with SSL, you need to obtain an SSL digital certificate for the destination machine. The certificate must be issued to the same computer name that you'll type to access the computer. That is, if you're running `Enter-PSSession -computerName DC01.COMPANY.LOC -UseSSL -credential COMPANY\Administrator`, then the certificate installed on DC01 must be issued to dc01.company.loc, or the entire process will fail. Note that the `-credential` parameter is mandatory in this scenario.

After getting your certificate, you need to install it into the Personal certificate store for the computer account—something best accomplished with the Certificates snap-in in the Microsoft Management Console (MMC) GUI. Simply double-clicking a certificate file will usually put it in your user account's Personal store, but that won't work.

With the certificate installed, you need to create an HTTPS listener on the computer, telling it to use the newly installed certificate. The step-by-step directions are extensive, and because this isn't something a lot of people will probably do, we don't cover them all here. Take a look at Don's *Secrets of PowerShell Remoting* guide (it's free) and you'll find step-by-step instructions including screenshots.

23.4.3 Mutual authentication via TrustedHosts

Using TrustedHosts is a slightly easier technique than using an SSL certificate, and it requires a lot less setup. But it's a bit more dangerous, because it basically shuts off mutual authentication for selected hosts. Before you try it, you need to be able to confidently state, "It is unthinkable that someone could impersonate one of these hosts or hack their DNS records." For internal computers on your intranet, for example, you might feel pretty confident of that.

Then you just need a way to identify the computers you'll trust without mutual authentication. In a domain, for example, that might be something like *.COMPANY.COM for all hosts in the Company.com domain.

This is an instance where you’re likely going to want to configure the setting for your entire domain, so here we give you the Group Policy instructions. You can use these same instructions for a single computer’s Local Security Policy.

In any GPO or in the Local Computer Policy editor, follow these steps:

- 1 Expand Computer Configuration.
- 2 Expand Administrative Templates.
- 3 Expand Windows Components.
- 4 Expand Windows Remote Management.
- 5 Expand WinRM Client.
- 6 Double-click Trusted Hosts.
- 7 Enable the policy and add your Trusted Hosts lists. Multiple entries can be separated by commas, such as *.company.com, *.sales.company.com.

NOTE Older versions of Windows might not have the template needed to display these settings in the Local Computer Policy, and older domain controllers might not have them in their Group Policy objects. For those situations, you can change the Trusted Hosts list in PowerShell. Run `help about_remote_troubleshooting` in the shell for instructions.

Now you’ll be able to connect to those machines without mutual authentication getting in the way. You must provide a `-Credential` parameter with all remoting commands used to connect to these computers; failure to do so will result in a failed connection attempt.

23.5 Lab

NOTE For this lab, you need a Windows 8 or Windows Server 2012, or later, computer running PowerShell v3 or later.

Create a remoting endpoint named TestPoint on your local computer. Configure the endpoint so that the SmbShare module is loaded automatically, but so that only the `Get-SmbShare` cmdlet is visible from that module. Also ensure that key cmdlets such as `Exit-PSSession` are available, but no other core PowerShell cmdlets can be used. Don’t worry about specifying special endpoint permissions or designating a “run as” credential.

Test your endpoint by connecting to it using `Enter-PSSession` (specify `localhost` as the computer name, and `TestPoint` as the configuration name). When connected, run `Get-Command` to ensure that only the designated handful of commands can be seen.

Note that this lab might be possible only on Windows 8, Windows Server 2012, and later versions of Windows; the SmbShare module didn’t ship with earlier versions of Windows.

23.6 Lab answer

```
#create the session configuration file in the current location
#this is one long line
New-PSSessionConfigurationFile -Path .\SMBShareEndpoint.pssc
    -ModulesToImport SMBShare -SessionType RestrictedRemoteServer
    -CompanyName "My Company" -Author "Jane Admin"
    -Description "restricted SMBShare endpoint" -PowerShellVersion '4.0'

#register the configuration
Register-PSSessionConfiguration -Path .\SMBShareEndpoint.pssc -Name TestPoint

#enter the restricted endpoint
Enter-PSSession -ComputerName localhost -ConfigurationName TestPoint
get-command
exit-pssession
```

Using regular expressions to parse text files

Regular expressions are one of those awkward topics. We often have students ask us to explain them, only to realize—halfway through the conversation—that they didn’t need regular expressions at all. A *regex*, as a regular expression is sometimes known, is useful in text parsing, which is something you end up doing a lot in UNIX and Linux operating systems. In PowerShell, you tend to do less text parsing—and you tend to need regexes less often. That said, we certainly know of times when, in PowerShell, you need to parse textual content such as an IIS log file. That’s how we cover regular expressions in this chapter: as a tool to parse text files.

Don’t get us wrong: There’s much more you can do with regular expressions, and we cover a few of those things at the end of this chapter. But to make sure you have a good expectation up front, let’s be clear that we don’t cover regular expressions comprehensively or exhaustively in this book. Regular expressions can get *incredibly* complicated. They’re an entire technology unto themselves. We’ll get you started, and try to do so in a way that’s immediately applicable to many production environments, and then we’ll give you some pointers for digging deeper on your own, if that’s your need.

Our goal with this chapter is to introduce you to regex syntax in a simplified fashion, and show you how PowerShell can use regular expressions. If you want to move on to more-complicated expressions on your own, you’re welcome to, and you’ll know how to use those within the shell.

24.1 The purpose of regular expressions

A regular expression is written in a specific language, and its purpose is to define a text pattern. For example, an IPv4 address consists of one to three digits, a period, one to three more digits, a period, and so forth. A regex can define that pattern, although it would accept an invalid address like 211.193.299.299. That's the difference between recognizing a text pattern and checking for the validity of the data.

One of the biggest uses of regular expressions—and the use we cover in this chapter—is to detect specific text patterns within a larger text file, such as a log file. For example, you might write a regex to look for the specific text that represents an HTTP 500 error in a web server log file, or to look for email addresses in an SMTP server log file. In addition to detecting the text pattern, you might use the regex to capture the matched text, enabling you to extract those email addresses from the log file.

24.2 A regex syntax primer

The simplest regex is an exact string of text that you want to match. Don, for example, is technically a regex, and in PowerShell it'll match DON, don, Don, DoN, and so on; PowerShell's default matching is case-insensitive.

Certain characters, however, have special meaning within a regex, and they enable you to detect patterns of variable text. Here are some examples:

- \w matches “word characters,” which means letters, numbers, and underscores, but no punctuation and no whitespace. The regex \won would match Don, Ron, and ton, with the \w standing in for any single letter, number, or underscore.
- \W matches the opposite of \w (so this is one example where PowerShell is sensitive to case), meaning it matches whitespace and punctuation—“nonword characters,” in the parlance.
- \d matches any digit from 0 through 9 inclusive.
- \D matches any nondigit.
- \s matches any whitespace character, including a tab, space, or carriage return.
- \S matches any nonwhitespace character.
- . (a period) stands in for any single character.
- [abcde] matches any character in that set. The regex d[aeiou]n would match don and dan, but not doum or deen.
- [a-z] matches one or more characters in that range. You can specify multiple ranges as comma-separated lists, such as [a-f, m-z].
- [^abcde] matches one or more characters that are not in that set, meaning the regex d[^aeiou] would match dns but not don.
- ? follows another literal or special character and matches exactly one instance of that character. So, the regex do?n would match don but would not match doon. It would also match dn because ? can also match zero instances of the preceding character.

- * matches any number of instances of the preceding character. The regex do*n would match both doon and don. It would also match dn because * also matches zero instances of the preceding character.
- + matches one or more instances of the preceding character. You'll see this used a lot with parentheses, which create a sort of subexpression. For example, the regex (dn)+o would match dndndndo because it matches repeating instances of the dn subexpression.
- \ (backslash) is the regex escape character. Use it in front of a character that normally has special meaning in the regex syntax, to make that character a literal. For example, the regex \. would match a literal period character, rather than allowing the period to stand in for any single character, as it normally does. To match a literal backslash, escape it with a backslash: \\.
- {2} matches exactly that many instances of the preceding character. For example, \d{1} matches exactly one digit. Use {2,} to match two or more, and use {1,3} to match at least one, but no more than three.
- ^ matches the beginning of the string. For example, the regex d.n would match don as well as pteranodon. But the regex ^d.n would match don but would not match pteranodon because the ^ makes the matching occur at the beginning of the string. This is a different use of ^ than in the previous example, where it was used with square brackets, [], to indicate a negative match.
- \$ matches the end of the string. For example, the regex .icks would match hicks and sticks (the match would technically be on ticks in that example), and would also match Dickson. But the regex .icks\$ would not match Dickson because the \$ indicates that the string should reach its end after the s.

There you have it—a whirlwind look at the basic regex syntax. As we wrote earlier, there's a lot more where that came from, but this is enough to get some basic work done. Let's look at some example regular expressions:

- \d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3} matches the pattern of an IPv4 address, although it'll accept illegal data like 432.567.875.000 as well as legal data like 192.169.15.12.
- \\\\w+(\\\\w+)+ matches a Universal Naming Convention (UNC) path. All the backslashes make that regex hard to read—which is one reason it's important to test and tweak your regular expressions before you rely on them in a production task.
- \w{1}\.\w+@company\.com matches a specific type of email address: first initial, a period, last name, and then @company.com. For example, d.jones@company.com would be a valid match. You do have to be a bit careful with these. For example, donald.jones@company.com.org would also be a valid match. The regex is fine with there being extra text before and after the matched portion. That's where the ^ and \$ anchors come into play in many situations.

NOTE You'll find more about basic regex syntax by running `help about_Regular_Expressions` in PowerShell. At the end of this chapter, we provide some additional resources for further exploration.

24.3 Using regex with -Match

PowerShell includes a comparison operator, `-Match`, and a case-sensitive cousin, `-CMatch`, that work with regular expressions. Here are some examples:

```
PS C:\> "don" -match "d[aeiou]n"
True
PS C:\> "dooon" -match "d[aeiou]n"
False
PS C:\> "dooon" -match "d[aeiou]+n"
True
PS C:\> "djinn" -match "d[aeiou]+n"
False
PS C:\> "dean" -match "d[aeiou]n"
False
```

Although it has many uses, we're primarily going to rely on `-Match` to test regular expressions and make sure they're working properly. As you can see, its left-hand operand is whatever string you're testing, and the right-hand operand is the regular expression. If there's a match, it outputs `True`; if not, you get `False`.

TRY IT NOW This is a good time to take a break from reading and try using the `-Match` operator. Run through some of the examples in the earlier syntax, and make sure you're comfortable using the `-Match` operator in the shell.

24.4 Using regex with Select-String

Now we reach the real meat of this chapter. We're going to use some IIS log files as examples, because they're exactly the kind of pure-text file that a regex is designed to deal with. It'd be nice if we could read these logs into PowerShell in a more object-oriented fashion but... well, we can't. So a regex it is.

Let's start by scanning through the log files to look for any `40x` errors. These are often File Not Found and other errors, and we want to be able to generate a report of the bad files for our organization's web developers. The log files contain a single line for each HTTP request, and each line is broken into space-delimited fields. We have some files that contain `401` and so forth as part of their filename—for example, `error401.html`—and we don't want those to be included in our results. We specify a regex such as `\s40[0-9]\s` because that specifies a space on either side of the `40x` error code. It should find all errors from `400` through `409` inclusive. Here's our command:

```
PS C:\logfiles> get-childitem -filter *.log -recurse |  
  select-string -pattern "\s40[0-9]\s" |  
  format-table Filename,LineNumber,Line -wrap
```

Notice that we change to the `C:\LogFiles` directory to run this command. We start by asking PowerShell to get all files matching the `*.log` filename pattern, and to recurse

subdirectories. That ensures that all three of our log files are included in the output. Then we use `Select-String` and give it our regex as a pattern. The result of the command is a `MatchInfo` object; we use `Format-Table` to create a display that includes the filename, the line number, and the line of text that contains our match. This can be easily redirected to a file and given to our web developers.

Next, we want to scan the files for all access by Gecko-based web browsers. Our developers tell us they've been having some problems with customers accessing the sites using those browsers, and they want to see which files in particular are being requested. They think they've narrowed the problem down to browsers running under Windows NT 6.2, meaning we're looking for user-agent strings that look something like this:

```
(Windows+NT+6.2;+WOW64;+rv:11.0)+Gecko
```

Our developers have stressed that the 64-bit thing isn't specific, so they don't want the log results limited to just `WOW64` user-agent strings. We come up with this regex: `6\.2;[\w\W]+\+Gecko`. Let's break that down:

- `6\.2;`—This is `6.2`; and notice that we escaped the period to make it a literal character rather than the single-character wildcard that a period normally indicates.
- `[\w\W]+\+`—This is one or more word or nonword characters—in other words, anything.
- `\+Gecko`—This is a literal `+`, then *Gecko*.

Here's the command to find matching lines from the log files, along with the first couple of lines of output:

```
PS C:\logfiles> get-childitem -filter *.log -recurse |  
  select-string -pattern "6\.2;[\w\W]+\+Gecko"  
  
W3SVC1\IISLOGS\ex120420.log:14:2012-04-20 21:45:04 10.211.55.30 GET  
/MyApp1/Testpage.asp - 80 - 10.211.55.29  
Mozilla/5.0+(Windows+NT+6.2;+WOW64;+rv:11.0)+Gecko/20100101+Firefox/11.0  
200 0 0 1125  
W3SVC1\IISLOGS\ex120420.log:15:2012-04-20 21:45:04 10.211.55.30 GET /TestPage.asp -  
80 - 10.211.55.29  
Mozilla/5.0+(Windows+NT+6.2;+WOW64;+rv:11.0)+Gecko/20100101+Firefox/11.0  
200 0 0 1 109
```

We left the output in its default format this time, rather than sending it to a format cmdlet.

As a final example, let's turn from IIS log files to the Windows Security log. Event log entries include a `Message` property, which contains detailed information about the event. Unfortunately, this information is formatted for easy human reading, not for easy computer-based parsing. We'd like to look for all events with ID 4624, which indicates an account logon (that number may differ in different versions of Windows; our example is from Windows Server 2008 R2). But we want to see only those events related to logons for accounts starting with `WIN`, which relates to computer accounts

in our domain, and whose account names end in TM20\$ through TM40\$, which are the specific computers we're interested in. A regex for this might look something like `WIN[\W\w]+TM[234][0-9]\$`. Notice how we need to escape the final dollar sign so that it isn't interpreted as an end-of-string anchor. We need to include `[\W\w]` (non-word and word characters) because it's possible for our account names to include a hyphen, which wouldn't match the `\w` word character class. Here's our command:

```
PS C:\> get-eventlog -LogName security | where { $_.eventid -eq 4624 } |  
    select -ExpandProperty message | select-string -pattern  
    "WIN[\W\w]+TM[234][0-9]\$"
```

We start by using `Where-Object` to keep only events with ID 4624. We then expand the contents of the `Message` property into a plain string, and pipe it to `Select-String`. Note that this will output the matching message text; if our goal was to output the entire matching event, we would have taken a different approach:

```
PS C:\> get-eventlog -LogName security | where { $_.eventid -eq 4624 -and  
    $_.message -match "WIN[\W\w]+TM[234][0-9]\$" }
```

Here, rather than outputting the contents of the `Message` property, we simply look for records where the `Message` property contains text matching our regex—and then output the entire event object. It's all about what you're after in terms of output.

24.5 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

Make no mistake about it, regular expressions can make your head spin, so don't try to create complex regexes right off the bat—start simple. Here are a few exercises to ease you into it. Use regular expressions and operators to complete the following:

- 1 Get all files in your Windows directory that have a two-digit number as part of the name.
- 2 Find all processes running on your computer that are from Microsoft, and display the process ID, name, and company name. Hint: pipe `Get-Process` to `Get-Member` to discover property names.
- 3 In the Windows Update log, usually found in `C:\Windows`, you want to display only the lines where the agent began installing files. You may need to open the file in Notepad to figure out what string you need to select.
- 4 Using the `Get-DNSClientCache` cmdlet, display all listings in which the `Data` property is an IPv4 address.

24.6 Further exploration

You'll find regular expressions used in other places in PowerShell, and many of them involve shell elements that we don't cover in this book. Here are some examples:

- The Switch scripting construct includes a parameter that lets it compare a value to one or more regular expressions.
- Advanced scripts and functions (script cmdlets) can utilize a regular expression-based input-validation tool to help prevent invalid parameter values.
- The -Match operator (which we covered briefly in this chapter) tests for string matches against a regular expression, and—something we didn’t share earlier—captures matched strings to an automatic \$matches collection.

PowerShell utilizes industry-standard regex syntax, and if you’re interested in learning more, we recommend *Mastering Regular Expressions* by Jeffrey E.F. Friedl (O’Reilly, 2006). A gazillion other regex books are out there, some of which are specific to Windows and .NET (and thus PowerShell), some of which focus on building a regex for specific situations, and so forth. Browse your favorite online bookstore and see if any books look appealing to you and your specific needs.

We also use a free online regex repository, <http://RegExLib.com>, which has numerous regex examples for a variety of purposes (phone numbers, email addresses, IP addresses, you name it). We’ve also found ourselves using <http://RegExTester.com>, a website that lets you interactively test regular expressions to get them dialed in exactly the way you need.

24.7 Lab answers

- 1 dir c:\windows | where {\$_.name -match "\d{2}"}
2 get-process | where {\$_.company -match "Microsoft"} |
Select Name, ID, Company
3 get-content C:\Windows\WindowsUpdate.log |
Select-string "Start [\w+\W+] +Agent: Installing Updates"
4 You could get by with a pattern that starts with one to three numbers followed by a literal period, like this:
get-dnsclientcache | where { \$_.data -match "^\d{1,3}\." }
Or you could match an entire IPv4 address string:
get-dnsclientcache | where
{ \$_.data -match "^\d{1,3}\.\d{1,3}\.\d{1,3}\.\d{1,3}" }

Additional random tips, tricks, and techniques

We're nearing the end of your month of lunches, so we'd like to share a few extra tips and techniques to round out your education.

25.1 Profiles, prompts, and colors: customizing the shell

Every PowerShell session starts out the same: the same aliases, the same PSDrives, the same colors, and so forth. Why not make the shell a little bit more customized?

25.1.1 PowerShell profiles

We've explained before that there's a difference between a PowerShell hosting application and the PowerShell engine itself. A hosting application, such as the console or the PowerShell ISE, is a way for you to send commands to the PowerShell engine. The engine executes your commands, and the hosting application is responsible for displaying the results. Another thing that the hosting application is responsible for doing is loading and running *profile scripts* each time the shell starts.

These profile scripts can be used to customize the PowerShell environment, by loading snap-ins or modules, changing to a different starting directory, defining functions that you'll want to use, and so forth. For example, here is the profile script that Don uses on his computer:

```
Import-Module ActiveDirectory  
Add-PSSnapin SqlServerCmdletSnapin100  
cd c:\
```

The profile loads the two shell extensions that Don uses the most, and it changes to the root of his C: drive, which is where Don likes to begin working. You can put any commands you like into your profile.

NOTE You might think there's no need to load the ActiveDirectory module, because PowerShell will implicitly load it as soon as Don tries to use one of the commands in that module. But that particular module also maps an AD: PSDrive, and Don likes to have that available as soon as the shell starts.

There's no default profile, and the exact profile script that you create will depend on how you want it to work. Details are available if you run `help about_profiles`, but you mainly need to consider whether you'll be working in multiple different hosting applications. For example, we tend to switch back and forth between the regular console and the PowerShell ISE, and we like to have the same profile running for both, so we have to be careful to create the right profile script file in the right location. We also have to be careful about what goes into that profile, because we're using it for both the console and the ISE; some commands that tweak console-specific settings such as colors can cause an error when run in the ISE.

Here are the files that the console host tries to load, and the order in which it tries to load them:

- 1 `$pshome\profile.ps1`—This will execute for all users of the computer, no matter which host they're using (remember that `$pshome` is predefined within PowerShell and contains the path of the PowerShell installation folder).
- 2 `$pshome\Microsoft.PowerShell_profile.ps1`—This will execute for all users of the computer if they're using the console host. If they're using the PowerShell ISE, the `$pshome\Microsoft.PowerShellISE_profile.ps1` script will be executed instead.
- 3 `$home\Documents\WindowsPowerShell\profile.ps1`—This will execute only for the current user (because it lives under the user's home directory), no matter which host they're using.
- `$home\Documents\WindowsPowerShell\Microsoft.PowerShell_profile.ps1`—This will execute for the current user if they're using the console host. If they're using the PowerShell ISE, the `$home\Documents\WindowsPowerShell\Microsoft.PowerShellISE_profile.ps1` script will be executed instead.

If one or more of these scripts doesn't exist, there's no problem. The hosting application will simply skip it and move on to the next one.

On 64-bit systems, there are variations for both 32- and 64-bit scripts, because there are separate 32- and 64-bit versions of PowerShell itself. You won't always want the same commands run in the 64-bit shell as you do in the 32-bit shell. By that we mean that some modules and other extensions are available for only one or the other architecture, so you wouldn't want a 32-bit profile trying to load a 64-bit module into the 32-bit shell, because it won't work.

Note that the documentation in `about_profiles` is different from what we've listed here, and our experience is that the preceding list is correct. Here are a few more points about that list:

- `$pshome` is a built-in PowerShell variable that contains the installation folder for PowerShell itself; on most systems, that's in `C:\Windows\System32\WindowsPowerShell\v1.0` (for the 64-bit version of the shell on a 64-bit system).
- `$home` is another built-in variable that points to the current user's profile folder (such as `C:\Users\Administrator`).
- We've used *Documents* to refer to the Documents folder, but on some versions of Windows it will be *My Documents*.
- We've written "no matter which host they're using," but that technically isn't true. It's true of hosting applications (the console and the ISE) written by Microsoft, but there's no way to force the authors of non-Microsoft hosting applications to follow these rules.

Because we want the same shell extensions to load whether we're using the console host or the ISE, we chose to customize `$home\Documents\WindowsPowerShell\profile.ps1`, because that profile is run for both of the Microsoft-supplied hosting applications.

TRY IT NOW Why don't you try creating one or more profile scripts for yourself? Even if all you put in them is a simple message, such as `Write "It Worked"`, this is a good way to see the different files in action. Remember that you have to close the shell (or ISE) and reopen it to see the profile scripts run.

Keep in mind that profile scripts are scripts and are subject to your shell's current execution policy. If your execution policy is `Restricted`, your profile won't run; if your policy is `AllSigned`, your profile must be signed. Chapter 17 discussed the execution policy and script signing.

25.1.2 Customizing the prompt

The PowerShell prompt—the `PS C:\>` that you've seen through much of this book—is generated by a built-in function called `Prompt`. If you want to customize the prompt, you can replace that function. Defining a new `Prompt` function is something that can be done in a profile script, so that your change takes effect each time you open the shell.

Here's the default prompt:

```
function prompt
{
    $(if (test-path variable:/PSDebugContext) { '[DBG] : ' }
    else { '' }) + 'PS ' + $(Get-Location) `n
    + $($if ($nestedpromptlevel -ge 1) { '>>' }) + '> '
```

This prompt first tests to see whether the `$DebugContext` variable is defined in the shell's VARIABLE: drive. If it is, this function adds `[DBG] :` to the start of the prompt.

Otherwise, the prompt is defined as `PS` along with the current location, which is returned by the `Get-Location` cmdlet. If the shell is in a nested prompt, as defined by the built-in `$nestedpromptlevel` variable, the prompt will have `>>` added to it.

Here's an alternative prompt function. You could enter this directly into any profile script to make it the standard prompt for your shell sessions:

```
function prompt {
    $time = (Get-Date).ToString("T")
    "$time [$env:COMPUTERNAME] :> "
}
```

This alternative prompt displays the current time, followed by the current computer name (which is contained within square brackets).

```
6:07 PM [CLIENT01] :>
```

Note that this uses PowerShell's special behavior with double quotation marks, in which the shell will replace variables (such as `$time`) with their contents.

25.1.3 Tweaking colors

In previous chapters, we've mentioned how stressed out we can get when a long series of error messages scrolls by in the shell. Don always struggled in English class when he was a kid, and seeing all that red text reminds him of the essays he'd get back from Ms. Hansen, all marked up with a red pen. Yuck. Fortunately, PowerShell gives you the ability to modify most of the default colors it uses.

The default text foreground and background colors can be modified by clicking the control box in the upper-left corner of PowerShell's window. From there, select Properties, and then select the Colors tab, which is shown in figure 25.1.

Modifying the colors of errors, warnings, and other messages is a bit trickier and requires you to run a command. But you could put this command into your profile, so that it executes each time you open the shell. Here's how to change the error message foreground color to green, which we find a lot more soothing:

```
(Get-Host).PrivateData.ErrorForegroundColor = "green"
```

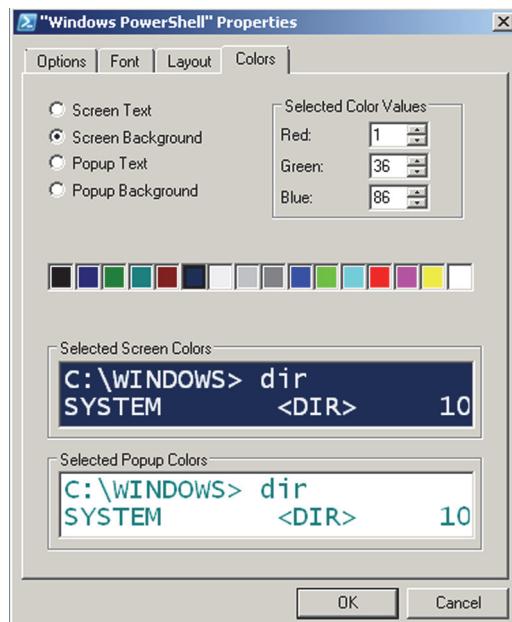

Figure 25.1 Configuring the default shell screen colors

You can change colors for the following settings:

- ErrorForegroundColor
- ErrorBackgroundColor
- WarningForegroundColor
- WarningBackgroundColor
- DebugForegroundColor
- DebugBackgroundColor
- VerboseForegroundColor
- VerboseBackgroundColor
- ProgressForegroundColor
- ProgressBackgroundColor

And here are some of the colors you can choose:

- Red
- Yellow
- Black
- White
- Green
- Cyan
- Magenta
- Blue

There are also dark versions of most of these colors: DarkRed, DarkYellow, DarkGreen, DarkCyan, DarkBlue, and so on.

25.2 Operators: -as, -is, -replace, -join, -split, -in, -contains

These additional operators are useful in a variety of situations. They let you work with data types, collections, and strings.

25.2.1 -as and -is

The -as operator produces a new object in an attempt to convert an existing object into a different type. For example, if you have a number that contains a decimal (perhaps from the result of a division operation), you can drop the decimal portion by converting, or *casting*, the number to an integer:

```
1000 / 3 -as [int]
```

The object to be converted comes first, then the -as operator, and then, in square brackets, the type you want to convert to. Types can include [string], [xml], [int], [single], [double], [datetime], and others, although those are probably the ones you'll use the most. Technically, this example of converting to an integer will round the fractional number to an integer, rather than just truncating the fractional portion of the number.

The `-is` operator works similarly: It's designed to return `True` or `False` if an object is of a particular type or not. Here are a few one-line examples:

```
123.45 -is [int]
"SERVER-R2" -is [string]
$True -is [bool]
(Get-Date) -is [datetime]
```

TRY IT NOW Try running each of these one-line commands in the shell to see the results.

25.2.2 `-replace`

The `-replace` operator is designed to locate all occurrences of one string within another and replace those occurrences with a third string:

```
PS C:\> "192.168.34.12" -replace "34","15"
192.168.15.12
```

The source string comes first, followed by the `-replace` operator. Then you provide the string you want to search for within the source, followed by a comma and the string you want to use in place of the search string. In the preceding example, we replace 34 with 15.

25.2.3 `-join` and `-split`

The `-join` and `-split` operators are designed to convert arrays to delimited lists, and vice versa.

For example, suppose you create an array with five elements:

```
PS C:\> $array = "one", "two", "three", "four", "five"
PS C:\> $array
one
two
three
four
five
```

This works because PowerShell automatically treats a comma-separated list as an array. Now, let's say you want to join this array together into a pipe-delimited string. You can do that with `-join`:

```
PS C:\> $array -join "|"
one|two|three|four|five
```

Saving that result into a variable will let you reuse it, or even pipe it out to a file:

```
PS C:\> $string = $array -join "|"
PS C:\> $string
one|two|three|four|five
PS C:\> $string | out-file data.dat
```

The `-split` operator does the opposite: It takes a delimited string and makes an array from it. For example, suppose you have a tab-delimited file containing one line and four columns. Displaying the contents of the file might look like this:

```
PS C:\> gc computers.tdf
Server1 Windows East      Managed
```

Keep in mind that `Gc` is an alias for `Get-Content`.

You can use the `-split` operator to break that into four individual array elements:

```
PS C:\> $array = (gc computers.tdf) -split "`t"
PS C:\> $array
Server1
Windows
East
Managed
```

Notice the use of the escape character, a backtick, and a *t* (`*t*) to define the tab character. This has to be in double quotes so that the escape character will be recognized.

The resulting array has four elements, and you can access them individually by using their index numbers:

```
PS C:\> $array[0]
Server1
```

25.2.4 -contains and -in

The `-contains` operator causes much confusion for PowerShell newcomers. You'll see folks try to do this:

```
PS C:\> 'this' -contains '*his*'
False
```

In fact, they mean to use the `-like` operator instead:

```
. PS C:\> 'this' -like '*his*'
True
```

The `-like` operator is designed for wildcard string comparisons. The `-contains` operator is used to test whether a given object exists within a collection. For example, create a collection of string objects, and then test whether a given string is in that collection:

```
PS C:\> $collection = 'abc','def','ghi','jkl'
PS C:\> $collection -contains 'abc'
True
PS C:\> $collection -contains 'xyz'
False
```

The `-in` operator does the same thing, but it flips the order of the operands so that the collection goes on the right, and the test object on the left:

```
PS C:\> $collection = 'abc','def','ghi','jkl'
PS C:\> 'abc' -in $collection
True
PS C:\> 'xyz' -in $collection
False
```

25.3 String manipulation

Suppose you have a string of text, and you need to convert it to all uppercase letters. Or perhaps you need to get the last three characters from the string. How would you do it?

In PowerShell, strings are objects, and they come with a great many methods. Remember that a method is a way of telling the object to do something, usually to itself, and that you can discover the available methods by piping the object to `gm`:

```
PS C:\> "Hello" | gm

TypeName: System.String
Name           MemberType
----           -----
Clone          Method
CompareTo     Method
Contains       Method
CopyTo         Method
EndsWith      Method
Equals         Method
GetEnumerator Method
GetHashCode   Method
GetType        Method
GetTypeCode   Method
IndexOf        Method
IndexOfAny    Method
Insert         Method
IsNormalized   Method
LastIndexOf   Method
LastIndexOfAny Method
Normalize      Method
PadLeft        Method
PadRight       Method
Remove         Method
Replace        Method
Split          Method
StartsWith     Method
Substring      Method
ToCharArray    Method
ToLower        Method
ToLowerInvariant Method
ToString       Method
ToUpper        Method
ToUpperInvariant Method
Trim           Method
TrimEnd        Method
TrimStart      Method
Chars          ParameterizedProperty
Length         Property

Definition
-----
System.Object Clone()
int CompareTo(System.Object value...)
bool Contains(string value)
System.Void CopyTo(int sourceIndex, int destinationIndex, int count)
bool EndsWith(string value), bool EndsWith(string value, StringComparison)
bool Equals(System.Object obj), bool Equals(string value, StringComparison)
System.CharEnumerator GetEnumerator()
int GetHashCode()
type GetType()
System.TypeCode GetTypeCode()
int IndexOf(char value), int IndexOf(char value, int startIndex)
int IndexOfAny(char[] anyOf), int IndexOfAny(char[] anyOf, int startIndex)
string Insert(int startIndex, string value)
bool IsNormalized(), bool IsNormalized(char value)
int LastIndexOf(char value), int LastIndexOf(char value, int startIndex)
int LastIndexOfAny(char[] anyOf), int LastIndexOfAny(char[] anyOf, int startIndex)
string Normalize(), string Normalize(char value)
string PadLeft(int totalWidth), string PadLeft(int totalWidth, char value)
string PadRight(int totalWidth), string PadRight(int totalWidth, char value)
string Remove(int startIndex, int endIndex)
string Replace(char oldChar, char newChar)
string[] Split(Params char[] separator)
bool StartsWith(string value), bool StartsWith(string value, StringComparison)
string Substring(int startIndex, int endIndex)
char[] ToCharArray(), char[] ToCharArray(char value)
string ToLower(), string ToLower(char value)
string ToLowerInvariant()
string ToString(), string ToString(char value)
string ToUpper(), string ToUpper(char value)
string ToUpperInvariant()
string Trim(Params char[] trimCharacters)
string TrimEnd(Params char[] trimCharacters)
string TrimStart(Params char[] trimCharacters)
char Chars(int index) {get;}
System.Int32 Length {get;}
```

Some of the more useful `String` methods include the following:

- `IndexOf()` tells you the location of a given character within the string:

```
PS C:\> "SERVER-R2".IndexOf("-")
```

- `Split()`, `Join()`, and `Replace()` operate similarly to the `-split`, `-join`, and `-replace` operators we described in the previous section. We tend to use the PowerShell operators rather than the `String` methods.

- `ToLower()` and `ToUpper()` convert the case of a string:

```
PS C:\> $computername = "SERVER17"
PS C:\> $computername.ToLower()
server17
```

- `Trim()` removes whitespace from both ends of a string; `TrimStart()` and `TrimEnd()` remove whitespace from the beginning or end of a string, respectively:

```
PS C:\> $username = "    Don "
PS C:\> $username.Trim()
Don
```

All of these `String` methods are great ways to manipulate and modify `String` objects. Note that all of these methods can be used with a variable that contains a string (as in the `ToLower()` and `Trim()` examples), or they can be used directly with a static string (as in the `IndexOf()` example).

25.4 Date manipulation

Like `String` objects, `Date` (or `DateTime`, if you prefer) objects come with a great many methods that allow date and time manipulation and calculation:

```
PS C:\> get-date | gm
```

Name	MemberType	Definition
Add	Method	<code>System.DateTime Add(System.TimeSpan ...)</code>
AddDays	Method	<code>System.DateTime AddDays(double value)</code>
AddHours	Method	<code>System.DateTime AddHours(double value)</code>
AddMilliseconds	Method	<code>System.DateTime AddMilliseconds(doub...)</code>
AddMinutes	Method	<code>System.DateTime AddMinutes(double va...)</code>
AddMonths	Method	<code>System.DateTime AddMonths(int months)</code>
AddSeconds	Method	<code>System.DateTime AddSeconds(double va...)</code>
AddTicks	Method	<code>System.DateTime AddTicks(long value)</code>
AddYears	Method	<code>System.DateTime AddYears(int value)</code>
CompareTo	Method	<code>int CompareTo(System.Object value), ...</code>
Equals	Method	<code>bool Equals(System.Object value), bo...</code>
GetDateTimeFormats	Method	<code>string[] GetDateTimeFormats(), strin...</code>
GetHashCode	Method	<code>int GetHashCode()</code>
GetType	Method	<code>type GetType()</code>
GetTypeCode	Method	<code>System.TypeCode GetTypeCode()</code>
IsDaylightSavingTime	Method	<code>bool IsDaylightSavingTime()</code>
Subtract	Method	<code>System.TimeSpan Subtract(System.Date...</code>
ToBinary	Method	<code>long ToBinary()</code>
ToFileTime	Method	<code>long ToFileTime()</code>
ToFileTimeUtc	Method	<code>long ToFileTimeUtc()</code>
ToLocalTime	Method	<code>System.DateTime ToLocalTime()</code>
ToLongDateString	Method	<code>string ToLongDateString()</code>
ToLongTimeString	Method	<code>string ToLongTimeString()</code>
ToOADate	Method	<code>double ToOADate()</code>

ToShortDateString	Method	string ToShortDateString()
ToShortTimeString	Method	string ToShortTimeString()
ToString	Method	string ToString(), string ToString(s...)
ToUniversalTime	Method	System.DateTime ToUniversalTime()
DisplayHint	NoteProperty	Microsoft.PowerShell.Commands.Displa...
Date	Property	System.DateTime Date {get;}
Day	Property	System.Int32 Day {get;}
DayOfWeek	Property	System.DayOfWeek DayOfWeek {get;}
DayOfYear	Property	System.Int32 DayOfYear {get;}
Hour	Property	System.Int32 Hour {get;}
Kind	Property	System.DateTimeKind Kind {get;}
Millisecond	Property	System.Int32 Millisecond {get;}
Minute	Property	System.Int32 Minute {get;}
Month	Property	System.Int32 Month {get;}
Second	Property	System.Int32 Second {get;}
Ticks	Property	System.Int64 Ticks {get;}
TimeOfDay	Property	System.TimeSpan TimeOfDay {get;}
Year	Property	System.Int32 Year {get;}
DateTime	ScriptProperty	System.Object DateTime {get;if ((& { ...

Note that the properties enable you to access just a portion of a `DateTime`, such as the day, year, or month:

```
PS C:\> (get-date).month
10
```

The methods enable two things: calculations and conversions to other formats. For example, to get the date for 90 days ago, we like to use `AddDays()` with a negative number:

```
PS C:\> $today = get-date
PS C:\> $90daysago = $today.AddDays(-90)
PS C:\> $90daysago
Saturday, July 24, 2016 11:26:08 AM
```

The methods whose names start with `To` are designed to provide dates and times in an alternative format, such as a short date string:

```
PS C:\> $90daysago.ToShortDateString()
7/24/2016
```

These methods all use your computer's current regional settings to determine the correct way of formatting dates and times.

25.5 Dealing with WMI dates

WMI tends to store date and time information in difficult-to-use strings. For example, the `Win32_OperatingSystem` class tracks the last time a computer was started, and the date and time information looks like this:

```
PS C:\> get-wmiobject win32_operatingsystem | select lastbootuptime
lastbootuptime
-----
20101021210207.793534-420
```

PowerShell's designers knew you wouldn't be able to easily use this information, so they added a pair of conversion methods to every WMI object. Pipe any WMI object to `gm` and you can see those methods at or near the end:

```
PS C:\> get-wmiobject win32_operatingsystem | gm

  TypeName: System.Management.ManagementObject#root\cimv2\Win32_OperatingSystem
Name                           MemberType  Definition
----                           -----------
Reboot                         Method     System.Management...
SetDateTime                     Method     System.Management...
Shutdown                       Method     System.Management...
Win32Shutdown                   Method     System.Management...
Win32ShutdownTracker            Method     System.Management...
BootDevice                      Property   System.String Boo...
...
PSStatus                        PropertySet PSStatus {Status,...}
ConvertFromDateTime              ScriptMethod System.Object Con...
Convert.ToDateTime                ScriptMethod System.Object Con...
```

We cut out most of the middle of this output so that you can easily find the `ConvertFromDateTime()` and `Convert.ToDateTime()` methods. In this case, what you start with is a WMI date and time, and you want to convert that to a normal date and time, so you do it like this:

```
PS C:\> $os = get-wmiobject win32_operatingsystem
PS C:\> $os.Convert.ToDateTime($os.lastbootuptime)
Thursday, October 20, 2015 9:02:07 PM
```

If you want to make that date and time information part of a normal table, you can use `Select-Object` or `Format-Table` to create custom, calculated columns and properties:

```
PS C:\> get-wmiobject win32_operatingsystem | select BuildNumber,__SERVER,
➥@{l='LastBootTime';e={$_.Convert.ToDateTime($_.LastBootupTime)}}

BuildNumber          __SERVER          LastBootTime
-----             -----           -----
7600               SERVER-R2        10/20/2015 9:02:07 PM
```

Dates are less of a hassle if you're using the CIM commands, because they automatically translate most date/time values into something human-readable.

25.6 Setting default parameter values

Most PowerShell commands have at least a few parameters that include default values. For example, run `Dir` by itself and it defaults to the current path, without you having to specify a `-Path` parameter. In PowerShell v3, you can also define your own defaults for any parameter on any command—or even on multiple commands. Your defaults apply only when the command is run without the parameters you specify; you can always override your defaults by specifying the parameter and values when you run the command.

Defaults are stored in a special built-in variable named `$PSDefaultParameterValues`. The variable is empty each time you open a new shell window, and it's meant to be populated with a hash table (which you could do in a profile script, to have your defaults always in effect).

For example, let's say you want to create a new credential object containing a user-name and password, and have that credential automatically apply to all commands that have a `-Credential` parameter:

```
PS C:\> $credential = Get-Credential -UserName Administrator
➥-Message "Enter Admin credential"
PS C:\> $PSDefaultParameterValues.Add('*:Credential',$credential)
```

Or, you might want to force only the `Invoke-Command` cmdlet to prompt for a credential each time it's run. In this case, rather than assigning a default value, you'd assign a script block that executes the `Get-Credential` command:

```
PS C:\> $PSDefaultParameterValues.Add('Invoke-Command:Credential',
➥{Get-Credential -Message 'Enter administrator credential'
➥-UserName Administrator})
```

You can see that the basic format for the `Add()` method's first argument is `<-cmdlet> :<parameter>`, and `<cmdlet>` can accept wildcards such as `*`. The second argument for the `Add()` method is either the value you want to make the default, or a script block that executes another command or commands.

You can always examine `$PSDefaultParameterValues` to see what it contains:

```
PS C:\> $PSDefaultParameterValues
Name          Value
----          -----
*:Credential  System.Management.Automation.PSCredential
Invoke-Command:Credential  Get-Credential -Message 'Enter administ
```

You can learn more about this feature by reading the shell's `about_parameters_default_values` help file.

Above and beyond

PowerShell variables are controlled by something called scope. We offered a brief introduction to scope in chapter 21, and it is something that plays into these default parameter values.

If you set `$PSDefaultParameterValues` at the command line, it'll apply to all scripts and commands run within that shell session. But if you set `$-PSDefaultParameterValues` within a script, it'll apply only to things done by that script. That's a useful technique, because it means you can start a script with a bunch of defaults, and they won't apply to other scripts, or to the shell in general.

This concept of “what happens in the script, stays in the script” is the heart of scope. You can read more about scope in the shell's `about_scope` help file, if you'd like to explore further on your own.

25.7 Playing with script blocks

Script blocks are a key part of PowerShell, and you've been using them quite a bit:

- The `-FilterScript` parameter of `Where-Object` takes a script block.
- The `-Process` parameter of `ForEach-Object` takes a script block.
- The hash table used to create custom properties with `Select-Object`, or custom columns with `Format-Table`, accepts a script block as the value of the `E`, or `Expression`, key.
- Default parameter values, as described in the previous section, can be set to a script block.
- Some remoting and job-related commands, including `Invoke-Command` and `Start-Job`, accept script blocks on their `-ScriptBlock` parameter.

So what is a script block? In general, it's anything surrounded by curly brackets, `{}`, with the exception of hash tables, which use curly brackets but are preceded by the `@` symbol. You can even enter a script block right from the command line and assign it to a variable. You can then use the call operator, `&`, to run the block:

```
PS C:\> $block = {  
    > get-process | sort -Property vm -Descending | select -first 10 }  
  
PS C:\> &$block
```

Handles	NPM (K)	PM (K)	WS (K)	VM (M)	CPU (s)	Id	ProcessName
680	42	14772	13576	1387	3.84	404	svchost
454	26	68368	75116	626	1.28	1912	powershell
396	37	179136	99252	623	8.45	2700	powershell
497	29	15104	6048	615	0.41	2500	SearchIndexer
260	20	4088	8328	356	0.08	3044	taskhost
550	47	16716	13180	344	1.25	1128	svchost
1091	55	19712	35036	311	1.81	3056	explorer
454	31	56660	15216	182	45.94	1596	MsMpEng
163	17	62808	27132	162	0.94	2692	dwm
584	29	7752	8832	159	1.27	892	svchost

You can do quite a bit more with script blocks. If you'd like to explore the possibilities on your own, read the shell's `about_script_blocks` help file.

25.8 More tips, tricks, and techniques

As we said at the outset of this chapter, this is an overview of some random little things that we need to show you, but that don't fit neatly into one of the previous chapters. Of course, you'll continue to pick up tips and tricks with the shell as you learn more about it and gain more experience with it.

You can check out our Twitter feeds too—@JeffHicks and @concentratedDon—where we routinely share tips and techniques that we discover and find useful. Websites such as [PowerShell.com](#) also offer mailing lists that include regular tips. And don't forget the forums at [PowerShell.org](#). Sometimes, learning bit by bit can be an easy way to become more proficient in a technology, so consider these and any other sources you run across as a way to incrementally and continually improve your PowerShell expertise.

Using someone else's script

Much as we hope you'll be able to construct your own PowerShell commands and scripts from scratch, we also realize that you'll rely heavily on the internet for examples. Whether you're repurposing examples from someone's blog, or tweaking a script you've found in an online script repository such as the PowerShell Code Repository (<http://PoshCode.org>), being able to reuse someone else's PowerShell script is an important core skill. In this chapter, we'll walk you through the process we use to understand someone else's script and make it our own.

THANKS Credit goes to Christoph Tohermes and Kaia Taylor, who provided us with scripts to use in this chapter. We deliberately asked them for less-than-perfect scripts that don't necessarily reflect all of the best practices we normally like to see. And in some instances we *worsened* their scripts to make this chapter better reflect the real world. We truly appreciate their contribution to this learning exercise!

Note that we've also selected these scripts specifically because they use advanced PowerShell features that we haven't taught you. Again, we think that's realistic: You're going to run across stuff that looks unfamiliar, and part of this exercise is about how to quickly figure out what the script is doing, even if you aren't fully trained on every technique the script uses.

26.1 The script

The following listing shows the complete script, which is entitled New-WebProject.ps1. This script is designed to work with Microsoft's IIS cmdlets, available in Windows Server 2008 R2 and later when the Web Services role is installed.

Listing 26.1 New-WebProject.ps1

```
param(
    [parameter(Mandatory = $true)]
    [string] $Path,
    [parameter(Mandatory = $true)]
    [string] $Name
)
$System = [Environment]::GetFolderPath ("System")
$script:hostsPath = ([System.IO.Path]::Combine($System, "drivers\etc\"))  
➡+ "hosts"
function New-localWebsite([string] $sitePath, [string] $siteName)
{
    try
    {
        Import-Module WebAdministration
    }
    catch
    {
        Write-Host "IIS Powershell module is not installed. Please install it
➡ first, by adding the feature"
    }
    Write-Host "AppPool is created with name: " $siteName
    New-WebAppPool -Name $siteName
    Set-ItemProperty IIS:\AppPools\$Name managedRuntimeVersion v4.0
    Write-Host
    if(-not (Test-Path $sitePath))
    {
        New-Item -ItemType Directory $sitePath
    }
    $header = "www."+$siteName+".local"
    $value = "127.0.0.1 " + $header
    New-Website -ApplicationPool $siteName -Name $siteName -Port 80
    ➡ -PhysicalPath $sitePath -HostHeader ($header)
    Start-Website -Name $siteName
    if(-not (HostsFileContainsEntry ($header)))
    {
        AddEntryToHosts -hostEntry $value
    }
}
function AddEntryToHosts ([string] $hostEntry)
{
    try
    {
        $writer = New-Object System.IO.StreamWriter($hostsPath, $true)
        $writer.WriteLine([Environment]::NewLine)
        $writer.WriteLine($hostEntry)
        $writer.Dispose()
    }
}
```

```

    catch [System.Exception]
    {
        Write-Error "An Error occured while writing the hosts file"
    }
}
function HostsFileContainsEntry ([string] $entry)
{
    try
    {
        $reader = New-Object System.IO.StreamReader($hostsPath + "hosts")
        while(-not($reader.EndOfStream))
        {
            $line = $reader.ReadLine()
            if($line.Contains($entry))
            {
                return $true
            }
        }
        return $false
    }
    catch [System.Exception]
    {
        Write-Error "An Error occured while reading the host file"
    }
}

```

First up is a parameter block, which you learned to create in chapter 21:

```

param(
    [parameter(Mandatory = $true)]
    [string] $Path,
    [parameter(Mandatory = $true)]
    [string] $Name
)

```

This parameter block looks a bit different, but it appears to be defining a `-Path` and a `-Name` parameter, each of which is mandatory. Fair enough. When you run this, you'll need to provide both pieces of information.

The next couple of lines are more mysterious:

```

$System = [Environment]::GetFolderPath ("System")
$script:hostsPath = ([System.IO.Path]::Combine($System, "drivers\etc\"))  
➥+"hosts"

```

These don't look like they're doing anything potentially dangerous—words like `GetFolderPath` don't cause us any alarm. To see what these do, we run them right in the shell:

```

PS C:\> $system = [Environment]::GetFolderPath ('System')
PS C:\> $system
C:\Windows\system32
PS C:\> $script:hostsPath = ([System.IO.Path]::Combine($system, "drivers\etc  
➥\"))+"hosts"
PS C:\> $hostsPath
C:\Windows\system32\drivers\etc\hosts
PS C:\>

```

The `$script:hostsPath` code is creating a new variable, so you have that in addition to the new `$system` variable. These two lines are setting up a folder path and file path. Make a note of these variables' contents so that you can refer to them as you progress through the script.

The remainder of the script consists of three functions: `New-LocalWebsite`, `AddEntryToHosts`, and `HostsFileContainsEntry`. A function is like a script within a script: Each one represents a packaged bit of functionality that you can call on. You can see that each one defines one or more input parameters, although they don't do so in a `Param()` block. Instead, they use an alternative parameter declaration technique that's legal only for functions: listing the parameters in parentheses (the same as a `Param` block) just after the function's name. It's kind of a shortcut.

If you scan through the script, you won't see any of these functions being called from the script itself, so if you were to run this script as is, nothing would happen. But inside the `New-LocalWebsite` function, you can see where the `HostsFileContainsEntry` function is being called:

```
if(-not (HostsFileContainsEntry ($header)))
{
    AddEntryToHosts -hostEntry $value
}
```

You can also see where `AddEntryToHosts` is being called by this code. It's all in an `If` construct. In the shell, you can run `help *if*` to learn more:

```
PS C:\> help *if*
Name          Category   Module
----          -----   -----
diff          Alias
New-ModuleManifest Cmdlet   Microsoft.PowerShell.Core
Test-ModuleManifest Cmdlet   Microsoft.PowerShell.Core
Get-AppxPackageManifest Function Appx
Get-PfxCertificate Cmdlet   Microsoft.PowerShell.S...
Export-Certificate Cmdlet   PKI
Export-PfxCertificate Cmdlet   PKI
Get-Certificate   Cmdlet   PKI
Get-CertificateNotificationTask Cmdlet   PKI
Import-Certificate Cmdlet   PKI
Import-PfxCertificate Cmdlet   PKI
New-CertificateNotificationTask Cmdlet   PKI
New-SelfSignedCertificate Cmdlet   PKI
Remove-CertificateNotification... Cmdlet   PKI
Switch-Certificate Cmdlet   PKI
Test-Certificate   Cmdlet   PKI
about_If          HelpFile
```

Help files are usually listed last, and there's one for `about_If`. Reading through it, you can learn about how this construct works. In the context of our example script, this is checking whether `HostsFileContainsEntry` returns `True` or `False`; if it's `False`, the `AddEntryToHosts` function is called. This structure suggests that `New-LocalWebsite` is the "main" function in this script, or the function you'd want to run to

make something happen. `HostsFileContainsEntry` and `AddEntryToHosts` seem to be utility functions that are called upon as needed by `New-LocalWebsite`. Let's focus on `New-LocalWebsite`:

```
function New-localWebsite([string] $sitePath, [string] $siteName)
{
    try
    {
        Import-Module WebAdministration
    }
    catch
    {
        Write-Host "IIS Powershell module is not installed. Please install it
➥ first, by adding the feature"
    }
    Write-Host "AppPool is created with name: " $siteName
    New-WebAppPool -Name $siteName
    Set-ItemProperty IIS:\AppPools\$Name managedRuntimeVersion v4.0
    Write-Host
    if(-not (Test-Path $sitePath))
    {
        New-Item -ItemType Directory $sitePath
    }
    $header = "www."+$siteName+".local"
    $value = "127.0.0.1 " + $header
    New-Website -ApplicationPool $siteName -Name $siteName -Port 80
    ➥ -PhysicalPath $sitePath -HostHeader ($header)
    Start-Website -Name $siteName
    if(-not (HostsFileContainsEntry ($header)))
    {
        AddEntryToHosts -hostEntry $value
    }
}
```

You might not understand that Try construct. A quick search of help (`help *try*`) reveals the `about_try_catch_finally` help file, which explains that everything in the Try portion might cause an error. If it does, the catch portion should execute. OK, that means the function is going to try to load the `WebAdministration` module, and if that doesn't work, it'll display an error message. Frankly, we think it should probably just exit the function entirely if an error occurs, but it doesn't do that, so if `WebAdministration` doesn't load, you can expect to see more errors. You should make sure `WebAdministration` is available before running this!

The `Write-Host` stuff is useful for helping you track the progress of the script. The next command is `New-WebAppPool`. Searching help reveals it to be part of the `WebAdministration` module, and the command's help file explains what it does. Next, `Set-ItemProperty` seems to be setting something in the `AppPool` that was just created.

The plain `Write-Host` command seems to be there just to put a blank line on the screen. OK, that's fine. If you look up `Test-Path`, you'll see that it tests whether a given path, in this case a folder, exists. If not, the script uses `New-Item` to create that folder.

A variable, \$header, is created that turns the \$siteName parameter into something like www.sitename.local, and the \$value variable is created to add an IP address. Then the New-WebSite command is run with a variety of parameters; you can read the help on that command to figure out what each parameter does.

Finally, the Start-WebSite command runs. The help file says that this command gets the website up and running. That's when you get to the HostsFileContains-Entry and Add-EntryToHosts commands. Those appear to make sure the new website, as listed in the \$value variable, is put into the computer's local HOSTS IP address-to-name lookup file.

26.2 It's a line-by-line examination

The process in the previous section is a line-by-line analysis of the script, and that's the process we suggest you follow. As you progress through each line, do the following:

- Identify variables, try to figure out what they'll contain, and write that down on a piece of paper. Because variables are often passed to command parameters, having a handy reference of what you think each variable contains will help you predict what each command will do.
- When you run across new commands, read their help and try to understand what they're doing. For Get- commands, try running them—plugging in any values that the script passes in variables to parameters—to see what output is produced.
- When you run across unfamiliar elements, such as if or [environment], consider running short code snippets inside a virtual machine to see what those snippets do (using a VM helps protect your production environment). Search for those keywords in help (using wildcards) to learn more.

Above all, don't skip a single line. Don't think to yourself, "Well, I don't know what that does, so I'll just keep going." Stop and find out what each line does, or what you think it does. That helps you figure out where you need to tweak the script to meet your specific needs.

26.3 Lab

NOTE For this lab, you need any computer running PowerShell v3 or later.

Listing 26.2 shows a complete script. See if you can figure out what it does and how to use it. Can you predict any errors that this might cause? What might you need to do in order to use this in your environment?

Note that this script should run as is, but if it doesn't on your system, do you think you can track down the cause of the problem? Keep in mind that you've seen most of these commands, and for the ones you haven't, there are the PowerShell help files. Those files' examples include every technique shown in this script.

Listing 26.2 Get-LastOn.ps1

```

function get-LastOn {
<#
.DESCRIPTION
Tell me the most recent event log entries for logon or logoff.
.BUGS
Blank 'computer' column
.EXAMPLE
get-LastOn -computername server1 | Sort-Object time -Descending |
Sort-Object id -unique | format-table -AutoSize -Wrap
ID          Domain      Computer Time
--          -----      ----- -----
LOCAL SERVICE    NT AUTHORITY        4/3/2012 11:16:39 AM
NETWORK SERVICE  NT AUTHORITY        4/3/2012 11:16:39 AM
SYSTEM          NT AUTHORITY        4/3/2012 11:16:02 AM
Sorting -unique will ensure only one line per user ID, the most recent.
Needs more testing
.EXAMPLE
PS C:\Users\administrator> get-LastOn -computername server1 -newest 10000
-maxIDs 10000 | Sort-Object time -Descending |
Sort-Object id -unique | format-table -AutoSize -Wrap

        }
    }
}
Get-LastOn

```

26.4 Lab answer

The script file seems to define two functions that won't do anything until called. At the end of the script is a command, Get-LastOn, which is the same name as one of the functions, so we can assume that's what is executed. Looking at that function, you can see that it has numerous parameter defaults, which explains why nothing else needs to be called. The comment-based help also explains what the function does. The first part of this function is using Get-Eventlog:

```
$eventsAndIDs = Get-EventLog -LogName security -Newest $Newest |
```

```
Where-Object {$_InstanceId -eq $logonEventNum -or $_InstanceId -eq  
$logoffEventNum} | Select-Object -Last $maxIDs -Property  
TimeGenerated,Message,ComputerName
```

If this were a new cmdlet, we'd look at help and examples. The expression seems to be getting the newest Security event logs. \$Newest comes from a parameter and has a default value of 5000. These event logs are then filtered by `Where-Object`, looking for two event log values, also from the parameter.

Next it looks like something is done with each event log in the `foreach` loop. Here's a potential pitfall: If the event log doesn't have any matching errors, the code in this loop will likely fail unless it has some good error handling.

In the `foreach` loop, it looks like other variables are getting set. The first one is taking the event object and piping it to something called `parseEventmessage`. This doesn't look like a cmdlet name, but we did see it as one of the functions. Jumping to it, we can see that it takes a message as a parameter and splits each one into an array. We might need to research the `-Split` operator.

Each line in the array is processed by another `foreach` loop. It looks like lines are split again, and there is a `try/catch` block to handle errors. Again, we might need to read up on that to see how it works. Finally, there is an `if` statement, where it appears that if the split-up strings are not empty, then a variable called `$props` is created as a hash table or associative array. This function would be much easier to decipher if the author had included some comments. Anyway, the parsing function ends by calling `New-Object`, another cmdlet to read up on.

This function's output is then passed to the calling function. It looks like the same process is repeated to get `$domain`.

Oh, look, another hash table and `New-Object`, but by now we should understand what the function is doing. This is the final output from the function and hence the script.

27

Never the end

We've come to nearly the end of this book, but it's hardly the end of your PowerShell exploration. There's a lot more in the shell to learn, and based on what you've learned in this book, you'll be able to teach yourself much of it. This short chapter will help point you in the right direction.

27.1 Ideas for further exploration

This book has focused on the skills and techniques that you need to be an effective PowerShell tool *user*. In other words, you should be able to start accomplishing tasks using all of the thousands of commands that are available for PowerShell, whether your needs relate to Windows, Exchange, SharePoint, or something else.

Your next step is to start combining commands to create automated, multistep processes, and to do so in a way that produces packaged, ready-to-use tools for other people. We call that *toolmaking*, and it's the topic of its own complete book, *Learn PowerShell Toolmaking in a Month of Lunches* (Manning, 2012). But even with what you've learned in this book, you can produce parameterized scripts that contain as many commands as you need to complete a task—that's the beginning of toolmaking.

What else does toolmaking involve?

- PowerShell's simplified scripting language
- Scope
- Functions, and the ability to build multiple tools into a single script file
- Error handling
- Writing help

- Debugging
- Custom formatting views
- Custom type extensions
- Script and manifest modules
- Using databases
- Workflows
- Pipeline troubleshooting
- Complex object hierarchies
- Globalization and localization
- Proxy functions
- Constrained remoting and delegated administration
- Using .NET

There's lots more, too. If you get interested enough and have the right background skills, you may even be a part of PowerShell's third audience: software developers. A whole set of techniques and technologies exists around developing for PowerShell, using PowerShell during development, and more. It's a big product!

27.2 “Now that I’ve read the book, where do I start?”

The best thing to do now is to pick a task. Choose something in your production world that you personally find repetitive, and automate it using the shell. You'll almost certainly run across things that you don't know how to do, and that's the perfect place to start learning.

Here are some of the things we've seen other administrators tackle:

- Write a script that changes the password that a service uses to log in, and have it target multiple computers running that service. (You could do this in a single command.)
- Write a script that automates new user provisioning, including creating user accounts, mailboxes, and home directories. Setting NTFS permissions with PowerShell is tricky, but consider using a tool like Cacls.exe or Xcacls.exe from within your PowerShell script, instead of PowerShell's native (and complex) Get-ACL and Set-ACL cmdlets.
- Write a script that manages Exchange mailboxes in some way—perhaps getting reports on the largest mailboxes, or creating charge-back reports based on mailbox sizes.
- Automate the provisioning of new websites in IIS, using the WebAdministration module included in Windows Server 2008 R2 and later (which also works with IIS 7 in Windows Server 2008).

The biggest thing to remember is to *not overthink it*. Don once met an administrator who struggled for weeks to write a robust file-copying script in PowerShell so that he could deploy content across a web server farm. “Why not just use Xcopy or Robocopy?”

Don asked. The administrator stared at Don for a minute and then laughed. He'd gotten so wrapped up in "doing it in PowerShell" that he forgot that PowerShell can use all of the excellent utilities that are already out there.

27.3 Other resources you'll grow to love

We spend a lot of time working with, writing about, and teaching PowerShell. Ask our families—sometimes we barely shut up about it long enough to eat dinner. That means we've accumulated a lot of online resources that we use daily and that we recommend to all of our students. Hopefully, they'll provide you with a good starting point as well.

- <http://powershell.org>—This should be your first stop. You'll find everything from Q&A forums to free e-books, free webinars to live educational events, and a lot more. It's a central gathering place for a big chunk of the PowerShell community, including a podcast that's run for years and years.
- <http://youtube.com/powershellorg> and <http://youtube.com/powershelldon>—PowerShell.org's YouTube Channel and Don's YouTube channel, respectively, have tons of free PowerShell videos, including sessions recorded at the PowerShell + DevOps Global Summit.
- <http://jdhitsolutions.com>—This is Jeff's all-purpose scripting and PowerShell blog.
- <http://donjones.com>—This is Don's personal blog, and he often includes PowerShell and related content.
- <http://devopscollective.org>—This is the parent organization for PowerShell.org, focused on the bigger-picture DevOps approach to IT management.

Students often ask if there are any other PowerShell books that we recommend. Two are *Learn PowerShell Toolmaking in a Month of Lunches* and *PowerShell in Depth* (both available from Manning). We authored or co-authored these books, so if you liked this book, those ones will probably work well for you also. We also recommend *PowerShell Deep Dives* (Manning, 2013), a collection of deep technical articles authored by PowerShell MVPs (proceeds from the book benefit the Save the Children charity, so please buy three copies). Finally, if you're a fan of video training, both of us have videos at <http://Pluralsight.com>, along with thousands of other IT-related videos.

PowerShell cheat sheet

This is our opportunity to assemble a lot of the little *gotchas* into a single place. If you're ever having trouble remembering what something is or does, flip to this chapter first.

28.1 Punctuation

There's no doubt that PowerShell is full of punctuation, and much of it has a different meaning in the help files than it does in the shell itself. Here's what it all means within the shell:

- ` The *backtick* is PowerShell's escape character. It removes the special meaning of any character that follows it. For example, a space is normally a separator, which is why `cd c:\Program Files` generates an error. Escaping the space, `cd c:\Program` Files`, removes that special meaning and forces the space to be treated as a literal, so the command works.
- ~ When the *tilde* is used as part of a path, this represents the current user's home directory, as defined in the `UserProfile` environment variable.
- () *Parentheses* are used in a couple of ways:
 - Just as in math, parentheses define the order of execution. PowerShell executes parenthetical commands first, from the innermost parentheses to the outermost. This is a good way to run a command and have its output feed the parameter of another command: `Get-Service -computerName (Get-Content c:\computernames.txt)`.

- Parentheses also enclose the parameters of a method, and they must be included even if the method doesn't require any parameters: `Change-Start-Mode('Automatic')`, for example, or `Delete()`.
- [] *Square brackets* have two main uses in the shell:
 - They contain the index number when you want to refer to a single object within an array or collection: `$services[2]` gets the third object from `-$services` (indexes are always zero-based).
 - They contain a data type when you're casting a piece of data as a specific type. For example, `$myresult / 3 -as [int]` casts the result as a whole number (integer), and `[xml]$data = Get-Content data.xml` will read the contents of `Data.xml` and attempt to parse it as a valid XML document.
- { } *Curly braces*, also called *curly brackets*, have three uses:
 - They contain blocks of executable code or commands, called *script blocks*. These are often fed to parameters that expect a script block or a filter block: `Get-Service | Where-Object { $_.Status -eq 'Running' }`.
 - They contain the key=value pairs that make up a new hash table. The opening brace is always preceded by an @ sign. In the following example, we use braces both to enclose the hash-table key=value pairs (of which there are two) and to enclose an expression script block, which is the value for the second key, e: `$hashtable = @{l='Label';e={expression}}`.
 - When a variable name contains spaces or other characters normally illegal in a variable name, braces must surround the name: `${My Variable}`.
- ' ' *Single quotation marks* contain string values. PowerShell doesn't look for the escape character, nor does it look for variables, inside single quotes.
- " " *Double quotation marks* contain string values. PowerShell looks for escape characters and the \$ character inside double quotes. Escape characters are processed, the characters following a \$ symbol (up to the next whitespace) are taken as a variable name, and the contents of that variable are substituted. For example, if the variable `$one` contains the value `World`, then `$two = "Hello $one `n"` will contain `Hello World` and a carriage return (``n` is a carriage return).
- \$ The *dollar sign* tells the shell that the following characters, up to the next whitespace, represent a variable name. This can be tricky when working with cmdlets that manage variables. Supposing that `$one` contains the value `two`, then `New-Variable -name $one -value 'Hello'` will create a new variable named `two`, with the value `Hello`, because the dollar sign tells the shell that you want to use the contents of `$one`. In contrast, `New-Variable -name one -value 'Hello'` would create a new variable, `$one`.
- % The *percent sign* is an alias for the `ForEach-Object` cmdlet. It's also the modulus operator, returning the remainder from a division operation.
- ? The *question mark* is an alias for the `Where-Object` cmdlet.

- > The *right angle bracket* is a sort of alias for the Out-File cmdlet. It's not technically a true alias, but it does provide for Cmd.exe-style file redirection: `dir > files.txt`.
- +, -, *, /, and % These *math operators* function as standard arithmetic operators. Note that + is also used for string concatenation.
- - The *dash*, or *hyphen*, precedes both parameter names and many operators, such as `-computerName` or `-eq`. It also separates the verb and noun components of a cmdlet name, as in `Get-Content`, and serves as the subtraction arithmetic operator.
- @ The *at sign* has four uses in the shell:
 - It precedes a hash table's opening curly brace (see *curly braces* in this list).
 - When used before parentheses, it encloses a comma-separated list of values that form an array: `$array = @(1,2,3,4)`. Both the @ sign and the parentheses are optional, because the shell will normally treat any comma-separated list as an array anyway.
 - It denotes a *here-string*, which is a block of literal string text. A here-string starts with `@"` and ends with `"@`, and the closing mark must be on the beginning of a new line. Run `help about_quoting_rules` for more information and examples. Here-strings can also be defined using single quotes.
 - It is PowerShell's splat operator. If you construct a hash table in which the keys match parameter names, and those values' keys are the parameters' values, then you can splat the hash table to a cmdlet. Don wrote an article for *TechNet Magazine* on splatting (<http://technet.microsoft.com/en-us/magazine/gg675931.aspx>).
- & The *ampersand* is PowerShell's invocation operator, instructing the shell to treat something as a command and to run it. For example, `$a = "Dir"` places the string `Dir` into the variable `$a`. Then `& $a` will run the `Dir` command.
- ; The *semicolon* is used to separate two independent PowerShell commands that are included on a single line: `Dir ; Get-Process` will run `Dir` and then `Get-Process`. The results are sent to a single pipeline, but the results of `Dir` aren't piped to `Get-Process`.
- # The *pound sign*, or *hash mark*, is used as a comment character. Any characters following #, to the next carriage return, are ignored by the shell. The angle brackets, < and >, are used as part of the tags that define a block comment: Use <# to start a block comment, and #> to end one. Everything within the block comment will be ignored by the shell.
- = The *equals sign* is the assignment operator, used to assign a value to a variable: `$one = 1`. It isn't used for quality comparisons; use `-eq` instead. Note that the equals sign can be used in conjunction with a math operator: `$var +=5` will add 5 to whatever is currently in `$var`.
- | The *pipe* is used to convey the output of one cmdlet to the input of another. The second cmdlet (the one receiving the output) uses pipeline parameter

binding to determine which parameter or parameters will receive the piped-in objects. Chapter 9 has a discussion of this process.

- / or \ A *forward slash* is used as a division operator in mathematical expressions; either the forward slash or backslash can be used as a path separator in file paths: C:\Windows is the same as C:/Windows. The *backslash* is also used as an escape character in WMI filter criteria and in regular expressions.
- . The *period* has three main uses:
 - It's used to indicate that you want to access a member, such as a property or method, or an object: \$_.Status will access the Status property of whatever object is in the \$_ placeholder.
 - It's used to *dot-source* a script, meaning that the script will be run within the current scope, and anything defined by that script will remain defined after the script completes: . c:\myscript.ps1.
 - Two dots (...) form the range operator, which is discussed later in this chapter. You will also see two dots used to refer to the parent folder in the filesystem, such as in the ..\ path.
- , Outside quotation marks, the *comma* separates the items in a list or array: "One", 2, "Three", 4. It can be used to pass multiple static values to a parameter that can accept them: Get-Process -computername Server1, Server2, Server3.
- : The *colon* (technically, two colons) is used to access static members of a class; this gets into .NET Framework programming concepts. [-datetime] ::now is an example (although you could achieve that same task by running Get-Date).
- ! The *exclamation point* is an alias for the -not Boolean operator.

We think the only piece of punctuation on a U.S. keyboard that PowerShell doesn't actively use for something is the caret (^), although those do get used in regular expressions.

28.2 Help file

Punctuation within the help file takes on slightly different meanings:

- [] *Square brackets* that surround any text indicate that the text is optional. That might include an entire command ([-Name <string>]), or it might indicate that a parameter is positional and that the name is optional ([-Name] <string>). It can also indicate both that a parameter is optional and, if used, can be used positionally ([[-Name] <string>]). It's always legal to use the parameter name, if you're in any doubt.
- [] *Adjacent square brackets* indicate that a parameter can accept multiple values (<string>[] instead of <string>).
- < > *Angle brackets* surround data types, indicating what kind of value or object a parameter expects: <string>, <int>, <process>, and so forth.

Always take the time to read the full help (add -full to the help command), because it provides maximum detail as well as, in most cases, usage examples.

28.3 Operators

PowerShell doesn't use the traditional comparison operators found in most programming languages. Instead, it uses these:

- -eq Equality (-ceq for case-sensitive string comparisons)
- -ne Inequality (-cne for case-sensitive string comparisons)
- -ge Greater than or equal to (-cge for case-sensitive string comparisons)
- -le Less than or equal to (-cle for case-sensitive string comparisons)
- -gt Greater than (-cgt for case-sensitive string comparisons)
- -lt Less than (-clt for case-sensitive string comparisons)
- -contains Returns True if the specified collection contains the object specified (\$collection -contains \$object); -notcontains is the reverse.
- -in Returns True if the specified object is in the specified collection (\$object -in \$collection); -notin is the reverse.

Logical operators are used to combine multiple comparisons:

- -not Reverses True and False (the ! symbol is an alias for this operator)
- -and Both subexpressions must be True for the entire expression to be True
- -or Either subexpression can be True for the entire expression to be True

In addition, there are operators that perform specific functions:

- -join Joins the elements of an array into a delimited string
- -split Splits a delimited string into an array
- -replace Replaces occurrences of one string with another
- -is Returns True if an item is of the specified type (\$one -is [int])
- -as Casts the item as the specified type (\$one -as [int])
- ... Is a range operator; 1..10 returns ten objects, 1 through 10
- -f Is the format operator, replacing placeholders with values: "{0}, {1}" -f "Hello", "World"

28.4 Custom property and column syntax

In several chapters, we showed you how to define custom properties by using `Select-Object`, or custom columns and list entries by using `Format-Table` and `-Format-List`, respectively. Here's that hash-table syntax.

You do this for each custom property or column:

```
@{label='Column_or_Property_Name';expression={Value_expression}}
```

Both of the keys, `Label` and `Expression`, can be abbreviated as `l` and `e`, respectively (be sure to type a lowercase `L` and not the number `1`; you could also use `n` for `Name`, in place of the lowercase `L`).

```
@{n='Column_or_Property_Name';e={Value_expression}}
```

Within the expression, the `$_` placeholder can be used to refer to the current object (such as the current table row, or the object to which you’re adding a custom property):

```
@{n='ComputerName';e={$_.Name}}
```

Both `Select-Object` and the `Format-` cmdlets look for the `n` (or `name` or `label` or `1`) key and the `e` key; the `Format-` cmdlets can also use `width` and `align` (those are for `-Format-Table` only) and `formatstring`. Read the help for `Format-Table` for examples.

28.5 Pipeline parameter input

In chapter 9, you learned that there are two types of parameter binding: `ByValue` and `ByPropertyName`. `ByValue` occurs first, and `ByPropertyName` occurs only if `ByValue` doesn’t work.

For `ByValue`, the shell looks at the type of the object that’s piped in. You can discover that type name by piping the object to `Get-Member` yourself. The shell then looks to see whether any of the cmdlet’s parameters accept that type of input and are configured to accept pipeline input `ByValue`. It’s not possible for a cmdlet to have two parameters binding the same data type in this fashion. In other words, you shouldn’t see a cmdlet that has two parameters, each of which accepts `<string>` input, both of which accept pipeline input `ByValue`.

If `ByValue` doesn’t work, the shell switches to `ByPropertyName`. Here, it looks at the properties of the piped-in object and attempts to find parameters with the exact same names that can accept pipeline input `ByPropertyName`. If the piped-in object has properties `Name`, `Status`, and `ID`, the shell will look to see whether the cmdlet has parameters named `Name`, `Status`, and `ID`. Those parameters must also be tagged as accepting pipeline input `ByPropertyName`, which you can see when reading the full help (`add -full` to the help command).

Let’s look at how PowerShell does this. For this example, we’ll refer to the *first cmdlet* and *second cmdlet*, assuming you have a command that looks something like `Get-Service | Stop-Service` or `Get-Service | Stop-Process`. PowerShell follows this process:

- 1 What is the `TypeName` of the objects produced by the first cmdlet? You can pipe the results of the cmdlet to `Get-Member` on your own to see this. For multipart type names such as `System.Diagnostics.Process`, remember just that last bit: `Process`.
- 2 Do any parameters of the second cmdlet accept the kind of object produced by the first cmdlet (read the full help for the second cmdlet to determine this: `help <cmdlet name> -full`)? If so, do they also accept that input from the pipeline using the `ByValue` technique? This is shown in the help file’s detailed information for each parameter.
- 3 If the answer to step 2 is yes, then the entire object produced by the first cmdlet will be attached to the parameter identified in step 2. You’re finished—do not continue to step 4. But if the answer to step 2 is no, continue to step 4.

- 4 Consider the objects produced by the first cmdlet. What properties do those objects have? You can see this, again, by piping the first cmdlet's output to `Get-Member`.
- 5 Consider the parameters of the second cmdlet (you'll need to read the full help again). Are there any parameters that (a) have the same name as one of the properties from step 4, and (b) accept pipeline input using the `ByPropertyName`-enabled technique?
- 6 If any parameters meet the criteria in step 5, the properties' values will be attached to the same-named parameters, and the second cmdlet will run. If there are no matches between property names and `ByPropertyName`-enabled parameters, the second cmdlet will run with no pipeline input.

Keep in mind that you can always manually enter parameters and values on any command. Doing so will prevent that parameter from accepting pipeline input in any way, even if it would normally have done so.

28.6 When to use `$_`

This is probably one of the most confusing things about the shell: When is the `$_` placeholder permitted?

This placeholder works only when the shell is explicitly looking for it and is prepared to fill it in with something. Generally speaking, that happens only within a script block that's dealing with pipeline input, in which case the `$_` placeholder will contain one pipeline input object at a time. You'll run across this in a few places:

- In the filtering script block used by `Where-Object`:

```
Get-Service | Where-Object {$_['Status -eq 'Running']}
```
- In the script blocks passed to `ForEach-Object`, such as the main `Process` script block typically used with the cmdlet:

```
Get-WmiObject -class Win32_Service -filter "name='mssqlserver'" |  
    ForEach-Object -process {$_['ChangeStartMode('Automatic')']}
```
- In the `Process` script block of a filtering function or an advanced function. Our other book, *Learn PowerShell Toolmaking in a Month of Lunches*, discusses these.
- In the expression of a hash table that's being used to create a custom property or table column. Refer to section 28.4 in this chapter for more details, or read chapters 8, 9, and 10 for a more complete discussion.

In every one of those cases, `$_` occurs only within the curly braces of a script block. That's a good rule to remember for figuring out when it's OK to use `$_`.

appendix: Review labs

This appendix provides three review labs, which you can work on after completing the designated chapters and labs from this book. These reviews are a great way to take a break in your learning process and to reinforce some of the most important things you've learned to that point. Suggested answers are at the back of this appendix.

Because the instructions for some of these lab tasks are more complex, we've broken them down into discrete task sections. We've also provided you with a list of hints at the start of each lab, to remind you about specific commands, help files, and syntax that you may need to complete the lab.

Review lab 1: chapters 1–6

NOTE To complete this lab, you will need any computer running PowerShell v3 or later. You should complete the labs in chapters 1 through 6 of this book prior to attempting this review lab.

HINTS:

- Sort-Object
- Select-Object
- Import-Module
- Export-CSV
- Help
- Get-ChildItem (Dir)

TASK 1

Run a command that will display the newest 100 entries from the Application event log. Do not use Get-WinEvent.

TASK 2

Write a command line that displays only the five top processes based on virtual memory (VM) usage.

TASK 3

Create a CSV file that contains all services, including only the service name and status. Have running services listed *before* stopped services.

TASK 4

Write a command line that changes the startup type of the BITS service to Manual.

TASK 5

Display a list of all files named `win*.*` on your computer. Start in the `C:\` folder. Note: you may need to experiment and use some new parameters of a cmdlet in order to complete this task.

TASK 6

Get a directory listing for `C:\Program Files`. Include all subfolders and files. Direct the directory listing to a text file named `C:\Dir.txt` (remember to use the `>` redirector, or the `Out-File` cmdlet).

TASK 7

Get a list of the 20 most recent entries from the Security event log, and convert the information to XML. Do not create a file on disk: Have the XML display in the console window.

Note that the XML may display as a single top-level object, rather than as raw XML data—that's fine. That's just how PowerShell displays XML. You can pipe the XML object to `Format-Custom` to see it expanded out into an object hierarchy, if you like.

TASK 8

Get a list of all event logs on the computer, selecting the log name, its maximum size, and overflow action, and then convert to CSV, but without writing to a log file. You may need to discover another CSV related cmdlet.

TASK 9

Get a list of services. Keep only the services' names, display names, and statuses, and send that information to an HTML file with a title of "Service Report". Have the phrase "Installed Services" displayed in the HTML file before the table of service information. If you can, display Installed Services with an `<H1>` html tag. Verify the file in a web browser.

TASK 10

Create a new alias, named `D`, which runs `Get-ChildItem`. Export just that alias to a file. Now, close the shell and open a new console window. Import that alias into the shell. Make sure you can run `D` and get a directory listing.

TASK 11

Display installed hotfixes that are either ‘Hotfix’ or ‘Update’, but not Security Update.

TASK 12

Run a command that will display the current directory that the shell is in.

TASK 13

Run a command that will display the most recent commands that you have run in the shell. Locate the command that you ran for task 11. Using two commands connected by a pipeline, rerun the command from task 11.

In other words, if Get-Something is the command that retrieves historical commands, 5 is the ID number of the command from task 11, and Do-Something is the command that runs historical commands, run this:

```
Get-Something      id 5 | Do-Something
```

Of course, those aren’t the correct cmdlet names—you’ll need to find those. Hint: both commands that you need have the same noun.

TASK 14

Run a command that modifies the Security event log to overwrite old events as needed.

TASK 15

Use the New-Item cmdlet to make a new directory named C:\Review. This is not the same as running Mkdir; the New-Item cmdlet will need to know what *kind* of new item you want to create. Read the help for the cmdlet.

TASK 16

Display the contents of this registry key:

```
HKCU:\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders
```

Note: “User Shell Folders” is not exactly like a directory. If you change into that “directory,” you won’t see anything in a directory listing. User Shell Folders is an *item*, and what it contains are *item properties*. There’s a cmdlet capable of displaying item properties (although cmdlets use singular nouns, not plural).

TASK 17

Find (but please do not run) cmdlets that can...

- Restart a computer
- Shut down a computer
- Remove a computer from a workgroup or domain
- Restore a computer’s System Restore checkpoint

TASK 18

What command do you think could change a registry value? Hint: it’s the same noun as the cmdlet you found for task 16.

Review lab 2: chapters 1–14

NOTE To complete this lab, you'll need any computer running PowerShell v3. You should complete the labs in chapters 1 through 14 of this book prior to attempting this review lab.

HINTS:

- Format-Table
- Invoke-Command
- Get-Content (or Type)
- Parenthetical commands
- @{label='column_header';expression={\$_ .property}}
- Get-WmiObject
- Where-Object
- -eq -ne -like -notlike

TASK 1

Display a list of running processes in a table that includes only the process names and ID numbers. Don't let the table have a large blank area between the two columns.

TASK 2

Run this:

```
Get-WmiObject -class win32_systemdriver
```

Now run that same command again, but format the output into a list that displays the driver short name, its display name, the path to the driver file, its start mode, and its current state. Display the path property as Path, not whatever the actual property is.

TASK 3

Have two computers (it's OK to use localhost twice) run this command:

```
Get-PSPProvider
```

Use Remoting to do this. Ensure that the output includes the computer names.

TASK 4

Use Notepad to create a file named C:\Computers.txt. In that file, put the following:

```
localhost  
localhost
```

You should have those two names on their own lines in the file—two lines total. Save the file and close Notepad. Then write a command that will list the running services on the computer names in C:\Computers.txt.

TASK 5

Query all instances of Win32_LogicalDisk that have a drivetype of 3. Display the drive letter, its size, free space, and the percent free space. Once that works, re-run the com-

mand to display only those instances that have 50 percent or more free disk space. You may have to adjust the percent free value in order to get a result on your computer.

Hint: to calculate free space percentage, it's `freespace/size * 100`.

Note that the `Filter` parameter of `Get-WmiObject` cannot contain mathematical expressions.

TASK 6

Display a list of all WMI classes in the `root\CIMv2` namespace that start with `win32` using the CIM cmdlets.

TASK 7

Display a list of all `Win32_Service` instances where the `StartMode` is `Auto` and the `State` is not `Running`.

TASK 8

Find a command that can send email messages. What are the mandatory parameters of this command?

TASK 9

Run a command that will display the folder permissions on `C:\`. You will find the output easier to read as a list.

TASK 10

Run a command that will display the permissions on every subfolder of `C:\Users`. Just the direct subfolders; you don't need to recurse all files and folders. You'll need to pipe one command to another command to achieve this. Then repeat the process for hidden folders.

TASK 11

Find a command that will start Notepad under a credential other than the one you've used to log into the shell.

TASK 12

Run a command that makes the shell pause, or idle, for 10 seconds.

TASK 13

Can you find a help file (or files) that explains the shell's various *operators*?

TASK 14

Using `Get-Winevent`, display a list of all log files that have entries and sort the results in descending order by the number of entries.

TASK 15

Run this command:

```
Get-CimInstance -Classname Win32_Processor
```

Study the default output of this command. Now, modify the command so that it displays in a table. The table should include each processor's number of cores, manufac-

turer, and name. Also include a column called “MaxSpeed” that contains the processor’s maximum clock speed.

TASK 16

Run this command:

```
Get-CimInstance -Classname Win32_Process
```

Study the default output of this command, and pipe it to Get-Member if you want. Now, modify the command so that only processes with a peak working set size greater than 100,000 are displayed, and only show the process name, its path, and all of the peak properties.

TASK 17

If you are running PowerShell 5 or later, use the Find-Module command to discover packages with a tag of Network. Display the modules’ names, versions, and descriptions.

Review lab 3: chapters 1–19

NOTE To complete this lab, you’ll need any computer running PowerShell v3. You should complete the labs in chapters 1 through 19 of this book prior to attempting this review lab. Start by answering the following questions:

- 1 What command would you use to start a job that runs entirely on your local computer?
- 2 What command would you use to start a job that was coordinated by your computer, but whose contents were processed by remote computers?
- 3 Is \${computer name} a legal variable name?
- 4 How could you display a list of all variables currently defined in the shell?
- 5 What command could be used to prompt a user for input?
- 6 What command should be used to produce output that normally displays on the screen, but that could be redirected to various other formats?

Now, complete the following tasks.

TASK 1

Create a list of running processes. The list should include only process name, ID, VM, and PM columns. Show the VM and PM values in megabytes. Put the list into an HTML-formatted file named C:\Procs.html. Make sure that the HTML file has an embedded title of “Current Processes”. Display the file in a web browser and make sure that title appears in the browser window’s title bar. The formula to calculate megabytes, displaying the value as a whole number, goes something like \$_.VM / 1MB as [int] for the VM property. Then see if you can re-import the file back into PowerShell.

TASK 2

Using WMI or the CIM cmdlets create a tab-delimited file named C:\Services.tdf that contains all services on your computer. "`t" (backtick *t* inside double quotes) is PowerShell's escape sequence for a horizontal tab. Include only the names, display name, status, start mode, and account.

TASK 3

First, prompt the user to enter a computername and save the results to a variable. Then using the CIM cmdlets query a computer (use the variable) for its operating system name, version number, when it last booted, and how long it has been running (uptime). Include the computername in your output. You can figure out the uptime by subtracting the last boot time from the current date and time.

TASK 4

Take your commands from the previous task and turn it into a parameterized script. Hopefully it is obvious that the computername is a good candidate. Include an alias of CN and make it mandatory. The output should show the same properties, but you may want to come up with a better display name for the operating system name property.

TASK 5

Find all installed products using WMI and with Win32_Product class. This might take a while to run so use a background job. When finished, get the results and display the product name, company, version, install date, and installation location in a grid view.

Answers

Review Lab 1**TASK 1**

```
Get-EventLog -LogName Security -Newest 100
```

TASK 2

```
Get-Process | Sort -Property VM -Descending | Select -First 5
```

TASK 3

```
Get-Service | Select -Property Name,Status |  
Sort -Property Status -Descending |  
Export-Csv services.csv
```

TASK 4

```
Set-Service -Name BITS -StartupType Automatic
```

TASK 5

```
Get-ChildItem -Path C:\ -Recurse -file -Filter 'Win*.*'
```

TASK 6

```
Get-ChildItem -Path 'c:\program files' -recurse | Out-File c:\dir.txt
```

TASK 7

```
Get-EventLog -LogName Security -Newest 20 | ConvertTo-XML
```

TASK 8

```
Get-EventLog -list | Select Log,MaximumKilobytes,OverflowAction |
    convertto-csv
```

TASK 9

```
Get-Service | Select -Property Name, DisplayName, Status |
ConvertTo-HTML -PreContent "<H1>Installed Services</H1>" -title
    "Service Report" | Out-File c:\services.html
```

TASK 10

```
New-Alias -Name D -Value Get-ChildItem -PassThru | Export-Alias c:\alias.xml
```

After opening a new PowerShell window...

```
Import-Alias c:\alias.xml
D
```

TASK 11

```
get-hotfix -description "Update", "Hotfix"
```

TASK 12

```
Get-Location or its alias pwd.
```

TASK 13

```
Get-History
```

After running this, locate the command that you ran for Task 11. You will need its ID number, which you will put in place of x in the next command:

```
Get-History -id x | Invoke-History
```

TASK 14

```
Limit-EventLog -LogName Security -OverwriteAction OverwriteAsNeeded
```

TASK 15

```
New-Item -Name C:\Review -Type Directory
```

TASK 16

```
Get-ItemProperty -Path
    'HKCU:\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell
Folders'
```

TASK 17

- Restart-Computer
- Stop-Computer
- Remove-Computer
- Restore-Computer

TASK 18

```
Set-ItemProperty
```

Review Lab 2

TASK 1

```
Get-Process | Format-Table -Property Name, ID -AutoSize
```

TASK 2

```
Get-wmiobject -class win32_systemdriver | select -property Name,Displayname, @{Name="Path";Expression={$_.pathname}},StartMode,State
```

TASK 3

```
Invoke-Command -ScriptBlock { Get-PSPower } -computerName Computer1,Computer2
```

TASK 4

```
Get-Service -computerName (Get-Content C:\Computers.txt)
```

TASK 5

```
Get-WmiObject -class Win32_LogicalDisk -Filter "drivetype=3" | Select DeviceID,Size,Freespace, @{Name="PctFree";Expression = {($_.freespace/$_.size)*100}} | where {$_.PctFree -gt 50}
```

TASK 6

```
get-cimclass -classname win32*
```

TASK 7

```
Get-WmiObject -class Win32_Service -filter "StartMode='Auto' AND State<>'Running'"
```

This expression will also work, but is not a recommended best practice as it isn't filtering as early as possible.

```
Get-WmiObject -class Win32_Service | Where-Object { $_.StartMode -eq 'Auto' -and $_.State -ne 'Running' }
```

TASK 8

```
Send-MailMessage (Read the full help to determine mandatory parameters.)
```

TASK 9

```
Get-ACL -Path C:\ | format-list
```

TASK 10

```
Get-ChildItem -path C:\Users | Get-ACL  
Get-ChildItem -path C:\Users -Directory -Hidden | Get-ACL
```

TASK 11

```
Start-Process
```

TASK 12

```
Start-Sleep -seconds 10
```

TASK 13

```
Help *operators*
```

TASK 14

```
get-winevent -ListLog * | where {$_.recordcount -gt 0} | sort RecordCount -Descending
```

TASK 15

```
Get-CimInstance -classname Win32_Processor |
    Select-Object -property Manufacturer,NumberOfCores,Name,@{
        name='MaxSpeed';expression={$_.MaxClockSpeed}}
```

TASK 16

```
Get-WmiObject -class Win32_Process -filter "PeakWorkingSetSize >= 100000" |
    Select Name,ExecutablePath,Peak*
```

TASK 17

```
find-module -tag network | Sort Name | Select Name,Version,Description
```

Review Lab 3

- 1** Start-Job
- 2** Invoke-Command
- 3** Yes
- 4** Read-Host
- 5** Write-Output

TASK 1

```
Get-Process | Select-Object -property Name,ID,VM,PM |
    ConvertTo-HTML -Title "Current Processes" | Out-File C:\Procs.html
```

TASK 2

```
Get-CimInstance -classname win32_service |
    Select Name,State,StartMode,Startname |
    Export-Csv c:\services.tdf -Delimiter "`t"
```

THEN TRY

```
import-csv C:\services.tdf -Delimiter "`t"
```

TASK 3

```
$computer = Read-Host "Enter a computername"

Get-CimInstance -ClassName Win32_Operatingsystem -CimSession $computer |
    Select Caption,Version,LastBootUptime,
    @{Name="Uptime";Expression={(Get-Date) - $_.lastBootUpTime}},
    PSComputername
```

TASK 4

Here is one possible script version:

```
[cmdletbinding()]
Param(
    [Parameter(Mandatory=$True,HelpMessage = "Enter a computer name")]
    [Alias("CN")]
    [string]$Computername
)

Write-Verbose "Getting Operating system information from $Computername."
```

```
Get-CimInstance -ClassName -CimSession $computername |
Select @{Name="OS";Expression={$_.Caption}},Version,LastBootUptime,
@{Name="Uptime";Expression={(Get-Date) - $_.lastBootUpTime}},
@{Name="Computername";Expression={$_.PSComputername} }

Write-Verbose "Done."
```

TASK 5

First create a job. This is one way:

```
get-wmiobject win32_product -asjob
```

Then receive the results:

```
$prod = Receive-job 31 -Keep
```

Finally, process them as necessary:

```
$prod | Select Name, Vendor, InstallDate, InstallLocation |
Out-GridView -Title "My Products"
```

Learn WINDOWS POWERSHELL IN A MONTH OF LUNCHES

THIRD EDITION

DON JONES and JEFFERY D. HICKS

PowerShell is both a scripting language and an administrative shell that lets you control and automate nearly every aspect of Windows. It accepts and executes commands interactively and you can write scripts to manage most Windows servers like Exchange, IIS, and SharePoint, as well as online services like Azure and Office 365.

Learn Windows PowerShell in a Month of Lunches, Third Edition is an innovative tutorial designed for busy IT professionals. Just set aside one hour a day—lunchtime would be perfect—for a month, and you'll be automating Windows tasks faster than you ever thought possible. This updated edition covers PowerShell features that run on Windows 7, Windows Server 2008 R2 and later, PowerShell v3 and later, and includes v5 features like PowerShellGet.

What's Inside

- Learn PowerShell from the beginning, no experience required!
- Covers PowerShell v3 and up, Windows 7, and Windows Server 2008 R2 and later
- Each lesson takes an hour or less

Experience with Windows administration is helpful. No programming or scripting experience needed.

Veteran PowerShell MVPs **Don Jones** and **Jeffery Hicks** bring years as successful trainers to this concise, easy-to-follow book.

To download their free eBook in PDF, ePub, and Kindle formats, owners of this book should visit manning.com/books/learn-windows-powershell-in-a-month-of-lunches-third-edition
